An Address

ON

THE EXISTENCE OF ORGANIC DISEASE IN THE ABSENCE OF OBVIOUS SYMPTOMS.

Delivered before the Wimbledon and District Medical Society on Feb. 13th, 1903,

By J. R. BRADFORD, M.D., F.R.C.P. Lond., F.R.S.,

PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

GENTLEMEN,—The *diseases which I wish to bring before* your notice this evening form one of the many groups included under the *general term of* "latent diseases," but this expression is liable to some ambiguity owing to the fact that it is used for widely different *conditions.* The expression "latent disease" is often applied *to the* period that may intervene between the infection of the patient and the production of obvious signs and symptoms. In some maladies, as, for instance, syphilis or hydrophobia, this period may be *unduly prolonged in exceptional circumstances, but I do* not propose to deal with the many problems connected with this subject this evening. In other instances gross organic diseases may be present without attracting the attention of the patient either by symptoms or physical signs, and it is well known, to quote an extreme case, that large external tumours may sometimes be present which must have obviously existed for a considerable period and yet the patient's attention has only been attracted to the condition perhaps for a few days. Again it is not uncommon for the onset of *acute* disease to be ushered in with extremely equivocal symptoms. Thus, to take a well-known illustration, the onset of pneumonia may be characterised by an almost complete absence of chest symptoms, together with the presence *of others of a meningeal* or abdominal type In these circumstances unless great care is exercised, very serious errors of diagnosis and treatment may be made.

Although perhaps all these conditions might fall within the title of this address I do not propose to discuss such diseases to-night but to restrict my observations to the consideration of the occurrence or presence of serious and generally chronic diseases where no marked symptoms are present but yet where a careful examination will not fail to reveal the presence of the malady. *The importance of the* subject is increased by the fact that in a very large proportion of such cases the insidious malady present is a fatal one and not uncommonly an immediately fatal one. For our [illegible] be as accurate as [illegible] or the purposes of [illegible] al.

Diseases may be [illegible] *of* ways, from an etiological or [illegible] d the latter in many instances, [illegible] ably the more sound and *scientific.* For the purposes of the *clinician it is* certainly more useful and probably equally accurate to employ a classification based on the natural history of diseases—in other words, a classification based on the character of the symptoms presented. One may *on this* basis divide most maladies into three great groups: the acute, the chronic, and the latent, based on the presence or absence and the severity, if present, of the symptoms. The importance of the thorough study of symptoms must never be overlooked, especially when we remember that in many diseases symptoms only are present and probably in all diseases symptoms are the initial manifestations of the disorders. [illegible] dependent on our [illegible] ence o[illegible] gnition [illegible] appreciation of [illegible] of symptoms than by the detection [illegible] *is this the case,* but it may be s[illegible] *as it often does,* on the extent [illegible] always to be accurately gauged by physical signs. The extent *of* the lesions of organic disease is usually greater than what would have been expected from the physical signs, notwithstanding the great value of these in the *recognition of disease. For* this reason, as well as for the preceding ones, the intelligent study of symptoms is a matter of fundamental importance.

Although most diseases can be divided into the acute, the chronic, and the latent, according to the violence, if *present, or the absence of symptoms, as the case* may be, it must not be overlooked that acute symptoms *may* be produced, not only by the onset of acute diseases, but also by chronic and sometimes also by diseases hitherto latent and therefore producing no *symptoms.* The development of acute symptoms in these conditions may be due to a variety of causes

1. In some instances the occurrence of acute *symptoms* in the course of chronic and especially of latent disease may be due to an acute exacerbation in the morbid process. Familiar instances of this may be seen in perforative peritonitis. The perforation of a *gastric or of a typhoid* ulcer will lead to the production of symptoms more or less characteristic of the condition, provided the perforation *occurs in a patient who* has *presented* the symptoms of the underlying chronic or acute disorder, as the case may be. In a considerable proportion of cases, however, such *perforation occurs* in patients who have shown no symptoms of gastric ulcer or of typhoid fever; in other words, in cases where these diseases have run a latent course The violent and acute symptoms characteristic of perforation occurring in such cases will produce a clinical picture which may be indistinguishable from that seen in such an acute disease as the *most violent form of appendicitis.* These diseases afford a very good illustration of the onset of acute symptoms being *sometimes* due to an exacerbation or sudden increase in the extent of the underlying lesion and not dependent on the onset of an acute disease in a previously healthy person.

2 The onset of *acute symptoms in latent disease is not,* however, always dependent on a sudden increase of the lesion, as in the instances mentioned; more often it is dependent merely on a progressive development of the underlying malady. The sudden occurrence of acute uræmia in chronic renal disease affords a good illustration of this mode of causation. It is often supposed that the sudden development of acute symptoms in latent and chronic diseases is to be regarded as a result of the development of an acute and additional lesion. Thus the occurrence of uræmia in chronic Bright's disease is sometimes looked upon as dependent on the development of acute nephritis. This, *however, is* by no means invariably the *case,* and both in *experimental* physiology and pathology *many instances are to be found* of the *occurrence* of sudden and violent symptoms as the *mere* result of a slowly progressive lesion. In the case of glands—such as the thyroid, the suprarenal, and the *pancreas—it is* well known that very large quantities of these *glands may* be removed experimentally without producing any marked result, and that the subsequent removal of a further small amount, and in some instances a very small amount, may be followed by the immediate production of all the effects characteristic of the total loss of the gland Thus *seven-eighths* of the pancreas may be *removed* without any appreciable ill-effects; trenching on the remaining eighth is immediately followed by the development of marked *results.* Removal of all the thyroidal and parathyroidal tissue, with the exception of one para thyroid, is *not necessarily* followed by permanent ill-effects; but the removal of that one para-thyroid or of all the para thyroid, leaving the thyroid, is immediately followed by the development *of the characteristic* phenomena of athyroidea. It can *be seen from* these illustrations that the sudden development of acute symptoms in the course of a chronic or latent *disease is not necessarily to* be regarded as indicative of the onset *of* an acute lesion.

3 The onset of acute symptoms in the course of diseases *hitherto latent may* be *dependent,* not so much on any further development of the initial lesion, but rather on the presence of a complication; many illustrative instances of this are *available in* clinical medicine. Diabetes mellitus may not uncommonly, especially in the middle-aged, run practically a latent course and the gross underlying disease *may not* be detected until diabetic coma ensues as the result [illegible] intercurrent illness or perhaps as a sequel to trau-[illegible] y a case of diabetes has not been [illegible] atient not having sought advice [illegible] mptoms until a complication, such as coma or gangrene, has ensued as the result perhaps of a trivial injury. Another familiar instance of the same class *of facts* is afforded by the occurrence of retention of urine

No. 4153.

revealing the presence of some chronic disease of the spinal cord, such as tabes dorsalis, which perhaps up to that time had not produced symptoms attracting notice.

From the above illustrations we see that the development of acute symptoms in the course of latent diseases is by no means uncommon, but the subject matter that I wish to bring before you more especially is the occurrence of latent diseases without obvious symptoms. From this point of view these latent diseases may be divided into two great groups—the first consisting of those instances where latent diseases occur as complications of other and obvious maladies, and the complication produces either no obvious symptoms, or else the symptoms produced by it are erroneously interpreted as dependent on the initial malady. The second group, which is equally, if not more, important, consists of the instances where the latent disease is not detected until complications have developed, the original latent malady being overlooked, either owing to the complete absence of symptoms or in some instances owing to their equivocal character.

Both of these groups are of great practical importance from the clinical point of view and although the immediate object of this address deals rather with the second group it will be convenient to consider shortly some characteristic illustrations of latent diseases occurring as complications of other maladies and producing no obvious symptoms. As an example of this the renal sequelæ occurring in diseases of the bladder and of other pelvic organs may be quoted. Both the mechanical and the septic complications affecting the kidneys in bladder and pelvic disease may be readily overlooked. A very considerable degree of hydronephrosis, even bilateral in its distribution, may be present as a result of obstruction without producing any more marked effects than a diminution in the specific gravity of the urine and an increase in the amount of urine passed. Pyelonephritis may also exist with little other change in the urine than the presence of a trace of albumin, together with the excretion of an increased quantity of urine of low specific gravity and slight evening pyrexia. The existence of either of these renal complications is a factor which has a profound influence on the prognosis of the underlying disease and also on the likelihood of the success or otherwise of even very simple operative procedures. These renal complications will serve as an illustration of a truly latent disease, often reaching a high degree of development without the production of any symptoms sufficiently important to attract the patient's notice.

Another malady of a widely different character, but which may be truly latent, is the well-known occurrence of latent cerebral abscess as a complication of ear disease. In such cases headache, vomiting, and other characteristic features of the malady may be completely absent and such patients may die with great suddenness from rupture of the abscess into the cerebral ventricles. This fatal event is not uncommon where there has been little reason for thinking that the patient was suffering from any grave disease. In many, but probably not in all, such cases the error of overlooking the existence of cerebral abscess may be avoided by a careful examination of the optic discs, as it is well known that a considerable degree of neuritis may be present without producing such an impairment of vision as to attract the notice of the patient.

Pericarditis is especially apt to run a latent course when it occurs as a complication of renal disease, especially of Bright's disease. In such instances there is often a further reason for the pericarditis being overlooked owing to the fact that pericarditis is frequently not the only complication present; uræmia in one or other of its many forms may coexist with it. It is exceptional for the latent pericarditis of renal disease to be unaccompanied by physical signs, although the characteristic pain and many of the other usual symptoms of pericarditis may be absent. A careful physical examination will usually reveal the existence of the complication, especially if we bear in mind the great frequency with which it occurs both as a complication of renal disease and as an accompaniment of uræmia, and hence examine our patients thoroughly.

Many other instances might be quoted of the occurrence of serious and sometimes fatal complications of gross organic disease with more or less complete absence of symptoms, but the above will suffice for our purpose.

In other cases serious complications occur which are overlooked owing to the symptoms produced being attributed not to the complication but to the underlying malady. One of the most important and striking e afforded by the occurrence of so-calle effusion in cases of valvular disease of the especially, perhaps, in cases of aortic regu latent pleural effusion of this type may dev siderable extent without producing any symptom attracting notice to the pleural ca in most cases no other effect than a gra dyspnœa is to be observed, and this d absence of a complete examination of the readily be attributed to the cardiac malady causes when it is of mechanical and re Strychnia has often been prescribed in lar relief of the dyspnœa of valvular disease w remedy was paracentesis thoracis. Another latent pleural effusion is extraordinarily li looked depends on the fact that it not inf without the occurrence of marked genera much stress cannot really be laid on the i all cases of cardiac dyspnœa of a careful e made to determine the presence or absence effusion.

Although latent diseases are often overlo occur as complications of declared maladies, group of cases described above where the *ab initio* is by far the more important from of view, as many of our most serious mistak and prognosis are made by overlooking such some instances, no doubt, it is impossibl diagnose but even to suspect the existen organic lesion and such cases are only re post-mortem room. Not infrequently, howev can be made, or, at any rate, a suspicion en the disease which is apparently acute is complication, development, or sudden ma previously existent latent malady. Instanc can be quoted from almost all varieties of propose in the remaining time only to deal w more striking illustrations.

Amongst acute specific maladies typhoid f that affords the most striking as well as the illustration of this tendency to run a laten clinicians are aware of cases of apparently forative peritonitis which are really cases of a typhoid ulcer where the typhoid a latent course or, at any rate, has produce symptoms. Many such a case is erroneo as a case of perforative peritonitis due to It is of great importance in all cases of forative peritonitis to cross-examine the pati order to determine whether symptoms of are really absent or, as is more often the they have been present, but of an equiv character. Whether rheumatic fever ever run course is perhaps open to question, but many where extensive cardiac lesions are present definite history can be obtained of any p affection of the joints. Somewhat similar seen also in the cases of the complications of di scarlet fever. Typical diphtheritic paralysis, degree of severity, is familiar to everyone as sionally where no definite history of a throat obtained. In the case of nephritis and Bright possibility of a more or less latent attack of often a consideration that is forced on us. It in the case of chronic rather than in that of that the most striking examples of the exist diseases are afforded to us. The morbid proc at the root of angina pectoris very commonly very high degree without the production of and it is well known that the first attack of may be fatal. Fatty degeneration of the he in its more severe forms, is also a malady w a strictly latent course and the same is und of aneurysms limited to the first part of sometimes in others involving the thoracic seen an instance of a large aneurysm of aorta which produced no symptoms of any it had eroded the bodies of four dorsal vert caused paraplegia. The fact that fatty degen heart is peculiarly apt to run a latent course i considerable practical importance owing difficulty hitherto experienced not only in d disease but also in excluding it. Latent fat

r as an accompaniment or complication of many
ell as being the sole morbid process present
lead to sudden death in patients who are
very seriously ill, as in some forms of alcoholic
lso in some cases of hepatic cirrhosis. I have
nt with hepatic cirrhosis to die suddenly from
ere there was no evidence of the patient being
nd where cardiac symptoms were conspicuously
same fatality may occur in cases of alcoholic
at in both these maladies the possibility of the
latent fatty heart must be considered. Some
serious and fatal of cardiac diseases are
a latent course and this is a fact of capital
n the diagnosis of these maladies.

lmonary affections latent maladies are not so
one that is most liable to occur and to be over-
ink, pleural effusion. Latent pleural effusion
ss, a malady that is very generally recognised
t by some authorities is supposed to be more
ociated with pulmonary tuberculosis than other
urisy. It is also well known that the effects
roduced by a latent pleural effusion are sometimes
nay first attract notice to underlying malignant
e lung or pleura. Phthisis is not very apt to
latent course, although we are all familiar with
ere the most extensive phthisical changes may
d *without* the presence of very marked and
ptoms. It is usual, however, in such cases for
have been present, but either to have been
r erroneously attributed to some other non-
affection.

rkable that peritonitis may not only exist as a
e but that the most severe and violent forms
s may sometimes be present without producing
symptoms. I have known of a patient with
uodenal ulcer who was suffering from general
ritonitis who repudiated any idea of being ill

de. I have known of an instance where laparo-
erformed with the idea of treating gastric dilata-
not only was an ulcer present which had not
cted, but where this ulcer was of such a size
ve nearly the whole of the posterior wall of the

t disease of the stomach, the colon, and the
y exist without producing any marked
ach a very high degree of development
any impairment of the general health.

It is true that this is exceptional, but its occurrence is sufficiently frequent for the fact to be borne in mind. Some years ago I saw a case of a man, aged 30 years, who came under observation for a slight enlargement of the umbilicus which was clearly of a malignant nature He presented no symptoms or physical signs of abdominal disease, but a few days afterwards succumbed to an attack of profuse hæmatemesis and a large primary carcinoma was present in the stomach. In this case the absence of symptoms was so complete that the patient refused to believe that there was anything seriously amiss with him and persisted in thinking that the induration of the umbilicus was dependent upon the irritation produced by a button. Profuse hæmorrhage may also be the first symptom produced by malignant disease of the rectum which may have reached a high degree of development without producing any local discomfort or any symptoms to attract notice. This is perhaps more especially the case where the disease occurs in elderly vigorous patients.

Many hepatic diseases are liable to run a latent course and in tropical countries this is not uncommonly the case with hepatic abscess. In this country, however, this is not a matter of any very great practical importance. Gall-stones probably produce no symptoms in the great majority of cases of their occurrence, and this is a point which must be always borne in mind in the diagnosis of the possible causes of jaundice. Although the mere presence of gall-stones does not in the majority of cases lead to symptoms, these are usually produced when there is any attempt at the passage of the stones. It is well known, however, that large stones may ulcerate through the gall-bladder into the intestine without the production of any symptoms indicative of obstruction of the bile-ducts. Hence in cases of intestinal obstruction from impaction of gall-stones a history of jaundice is not to be expected. Perhaps the most striking, and certainly the most common, instance of latent disease of the liver is afforded by cirrhosis in its many forms and especially perhaps by alcoholic or atrophic cirrhosis. It is well known that symptoms are not produced in this malady until the disease has advanced to a very great extent and, in fact, they ought to be called terminal symptoms owing to the period of the disease at which they are present. This is especially true of ascites and to a less extent of hæmatemesis, but it must be remembered that a high degree of hepatic *cirrhosis may exist for many years* and death may occur as an indirect result of some intercurrent illness. It is from this point of view that the recognition of the latent *course* that *hepatic cirrhosis* is apt to run is especially important. A patient may suffer from hepatic cirrhosis with no apparent ill effects for an unknown but prolonged period *and then as the sequel of an* attack of some intercurrent disease, such as influenza or typhoid fever (to quote instances which have fallen under my own observa-
symptoms dependent on
evelop and rapidly prove
's not occur during the
fatal.
height of the intercurrent affection but subsequently to it and during convalescence.

Another remarkable group of cases of rather uncertain nature is afforded by patients who come under observation suffering from acute general peritonitis apparently dependent on perforation, but where no perforation is found post mortem but a high degree of atrophic cirrhosis. Two such instances have fallen under my observation and both in
children where there was
health prior to the sudde
and the violence of this in
of appendicitis or some oth
No perforations were found at the post-mortem examinations, but on the other hand there was extensive hepatic cirrhosis together with acute general suppurative peritonitis.

Amongst cerebral affections, tumor cerebri, meningitis, and aneurysm of the large cerebral vessels all afford illustration of the existence of very grave organic disease without the production of symptoms. Aneurysm of the cerebral vessels is extraordinarily liable to produce no symptoms for a more or less prolonged period, in some instances not until the fatal rupture, and in other cases the
produced are so equivocal as to render recognition
sible. I have known of a
r artery where the initial
the persistence of this for a
irregularity of pulse and
retention of urine to be followed very shortly by the coma

dependent on the rupture of the aneurysm. The existence of tumor cerebri without the production of obvious symptoms is so well known that everyone appreciates the difficulty of excluding with certainty the presence of tumour.

In the case of meningitis we meet with a remarkable instance of the existence of a grave and fatal disease without the production in some instances of the characteristic features of the malady. This absence of symptoms may occur not only in the acute disease but also in the chronic form, or, to be more accurate, in the condition which may remain as a result of a former attack of acute meningitis. Instances are known of diffuse suppurative meningitis where the onset of symptoms ultimately has been so sudden as to suggest the occurrence of a vascular lesion or even such a condition as meningeal hæmorrhage and where, as a result either of operative interference or post-mortem observation, it is certain that the condition must have existed for a considerable time before the occurrence of the symptoms. Every physician is familiar with cases of meningitis where the absence of the characteristic features of the disease has led to an erroneous diagnosis of hysteria or even malingering. There is a rare form of meningitis, of which three instances have been seen by me, where the patient may recover from an acute illness characterised by headache, fever, retraction of the head, with vomiting and other symptoms suggesting the presence of meningitis. Nothwithstanding their recovery and the more or less complete absence of symptoms such patients die suddenly after a variable interval of apparent recovery of health. In one instance such a patient presented occasional vomiting but otherwise seemed perfectly well and was up and about. The post-mortem examinations in all these three cases showed thickening and opacity of the membranes at the base and distension of the fourth ventricle. None of them were really diagnosed, although in one the condition was suspected on account of the history of the acute illness and owing to the presence of some optic neuritis. These cases illustrate the manner in which the effects produced by the acute meningitis may lead to a condition that is rapidly fatal although not productive of marked symptoms.

Many diseases of the spinal cord, meninges, and even of the spinal column may not only exist but may reach a very high degree of development without the production of any characteristic symptoms. Thus a perforating ulcer or Charcot's joint may be the first evidence of the existence of such a chronic disease as tabes or syringomyelus, and fracture of the spine as the result of a sudden movement may be the first unequivocal evidence of the existence of sarcoma or other malignant disease of the bones. Again, the apparently sudden formation of a large psoas abscess may be the first indication of spinal caries, and in this malady it is not uncommon for paraplegia, or rather weakness of the legs, to be an early symptom of primary mischief in the bones.

Diseases of the kidneys afford perhaps the most striking instances of the existence of grave organic lesions without the presence necessarily of marked and obvious symptoms. We have already seen that diseases of these organs may occur in an insidious manner as consequences or sequels of pelvic diseases without affording sufficient symptoms to attract attention. Kidney diseases afford perhaps also the most frequent examples of the diseases grouped under the second heading of this address—viz, those where the original malady is overlooked until the occurrence of complications. Almost all the common affections of the kidney may exist in a latent form and advance to a high degree without producing marked symptoms. This is not only seen in such affections as hydronephrosis and pyelonephritis, but also in cystic disease, and most important of all in granular kidney and in certain forms of Bright's disease The recognition of what may for shortness be called latent Bright's disease and latent granular kidney is of great practical importance owing to the beneficial effects that may be obtained as a result of the proper treatment of these diseases.

The occurrence of bilateral cystic disease without the development of marked symptoms is more a matter of theoretical interest than of great practical importance inasmuch as so little can be done for the disease when recognised. It is not uncommon for patients to come under observation on account of vague abdominal symptoms or for such a symptom as gradually increasing constipation and then on examination of the abdomen for the presence of cystic disease of the kidneys to be revealed, and in such instances the large size of the renal tumours indicates that the malady must have for a very considerable time. In other instances, as known, extensive and bilateral cystic disease symptoms of any kind and is discovered, so to say, dentally where not suspected in the post-mortem Uræmia in one of its many forms, and even in its most form, may be the first intimation of the existence of disease of the kidneys. The affection usually d granular kidney is also one that is constantly under our observation in a more or less latent form this is the case both where the renal affection part and parcel of a widespread arterial d and also in other instances where the main of the pathological process is on the kidney No doubt in the large majority of both classes of patients careful cross-examination may elicit some of ill-health prior to the development of the that compels the patient to seek advice, but in a great cases such symptoms are elicited with difficulty and after the development of the complication. It is not un for these symptoms to be of a vague character, such failure in the general health and strength or possibly impairment of the general nutrition, symptoms which be due to a great variety of causes and which do not at sight suggest a possible renal origin. A common com tion that leads to the recognition of the underlying ma is cerebral hæmorrhage, but in these cases the cer hæmorrhage is usually profuse and often fatal, and t fore the recognition of the underlying cause is of no ava

In another and perhaps more striking group of cas symptoms of sufficient importance to attract attentio the part of the patient may occur until the onset of epi form seizures or some other manifestations of uræ Numerous instances have occurred where patients died from acute uræmia after an illness lasting in some c a few hours and in others only a few days. It is alwa worth while to examine carefully for the presence of granular kidney in cases of sudden epileptiform seiz occurring for the first time in a patient of the age li to granular kidney I would especially draw your att tion to the fact that one of the most fatal forms chronic Bright's disease not uncommonly runs what is all intents and purposes a latent course, no sympto being produced until the terminal or fatal illness wh may last but a few days. This form of Bright's dise is most commonly seen in young adults and is char terised post mortem by the presence of small wh or mottled kidneys with a rough granular surface. Th patients in my experience do not present, as a rule, a history of a definite attack of acute Bright's disease char terised by dropsy and they are often quite unable to give a information by means of which the onset of the disease c be ascertained, although doubtless in some instances it i sequel of a former attack of acute Bright's disease, but I not think that it is so in all for the reason just mention A very considerable proportion of these cases do not co under observation until a fatal complication is present a this complication is especially likely to be uræmia. In so instances one of the so-called uræmic skin eruptions has b the first symptom that has attracted notice. In others first symptom has been failure of vision owing to the devel ment of retinal hæmorrhages and marked optic neuritis, in others some inflammatory complication has superven more especially pericarditis. But uræmia in all its fo is unquestionably the most important and, I think, most common complication. Thus a patient may be s suffering from what is apparently an epileptiform seizure perhaps presenting no very marked signs of ill-health, onset of the fits having been quite sudden. Yet on exam tion the presence of marked arterial changes albuminuric retinitis and the secretion of a copious di urine containing a large quantity of albumin all p to the conclusion that the disease is not only la but has really existed for some considerable time, o for years. In the great majority of these pati it would not be correct to state that all symp are absent; there is often some progressive failure health and strength, but even this in some cases is marked and I have known the disease to be fatal uræmic complications occurring at a time when the aspect of the patient would by no means suggest the bility of the presence of a grave renal disease. Thus, a man, 25 years of age, presenting no history of a former illness, came under observation on account of neuras oms associated with, and apparently due to, business s. A few days afterwards a papular eruption appeared r the skin of the trunk and examination of the urine that it was of low specific gravity, abundant in ty, and contained a large amount of albumin, notanding

were no

uræmia

n 48 hours. This form of Bright's disease may very be overlooked unless the urine be examined in a fashion. The state of the optic discs will also often evidence of the existence of the malady, as it is le that where it has existed for any length of time s both in the retina and in the retinal vessels can be d. One of the reasons leading to the malady being oked is perhaps the fact that dropsy is not a marked and may even be entirely absent and, according experience, this is generally the case. The state of art and of the vessels will often raise a suspicion of esence of this form of chronic Bright's disease, but

be detected by the finger are

iac hypertrophy may unques-

t. The other form of chronic

large white kidney, is not so

run a latent course and owing to the anæmia pro- and the frequency of dropsy the recognition of the y is easy.

onclusion, the great lesson that is to be learnt from ccurrence of all these numerous varieties of latent e is the one that most of them can be detected or at ate suspected as the result of a complete physical nation. In other words, it is the symptoms that are , not the physical signs. The only precaution that it ssary to take is to examine as far as possible all the of the body and not to be contented with a physical nation restricted to those parts to which the patients ttention. Thus many a patient complaining of heart oms perhaps dependent on organic disease of the is really suffering from renal disease with secondary difficulties; the real cause of the disease would be etely overlooked if the examination were confined to gan to which the patient's symptoms are referred.

MEDICINE, ETC.

LECTURE III.[1]

Delivered on March 24th.

NS, OTHER THAN ANTITOXIC AND BACTERICIDAL, OF CURATIVE SERA.

PRESIDENT AND GENTLEMEN,—We have seen that ntroduction of the serum of one animal into the of another, especially of a different species, leads formation of antidotes to that particular kind of In some instances, indeed, the serum of one animal e toxic for another. The introduction, therefore, of a ty of horse's serum into the human body may not be— , is not—always a matter of indifference. We know the case of diphtheria antitoxin a certain percentage es have eruptions, pains of the joints, &c., which obably to be assigned to the alien serum. Perhaps the juvenile serum is of

rimitive nature than the adult,

and prophylactic injections of

than those already grown up.

sera these side-issues do not

Nor will any harm arise from

a dose beyond what is necessary for mere neutralisation of the toxin; on the contrary, the excess may dissociate a union of toxin and cell already completed. There is not at present any evidence to show that the toxin formed by the bacillus diphtheriæ in the human body is not efficiently neutralised by the antitoxin formed in the horse's tissues.

With bactericidal sera the case is rather different, because for their efficient action both amboceptor and complement are required. It is obvious that efficiency will be attained only if both components are present in sufficient quantity, but it is the number of amboceptors resulting from the process of immunisation which will determine to a large extent the potency of the bactericidal serum, since they are present in normal blood only in small quantity. The complement, as we know, is much more unstable and may, on keeping of the bactericidal serum, either disappear or be converted into complementoid. On the other hand, complement is present in quantity and variety in normal serum, so that the introduction of amboceptors alone in the bactericidal serum will often suffice for its efficient action. But the quantitative relations of amboceptor and complement are of extreme importance. It has been known for some time that a medium dose of a bactericidal serum may save an animal from a lethal infection whilst a larger or smaller quantity fails to do so. The explanation seems to be as follows: If the two components are present in corresponding quantities the amboceptor will unite with the bacterium by its haptophore group, the complement will then fit into the complementophile group of the amboceptor and the bacterium will be destroyed. But with an excess of amboceptors an alteration of equilibrium takes place and the affinity of the complementophile group of the engaged amboceptor for the complement may be altered. If increased there is no harm done, because the complements will unite with the already engaged—viz., effective—amboceptors. If the affinity remains equal the complements will be equally distributed and only half will take part in the bactericidal action and the efficiency of the serum will be correspondingly reduced. If the affinity is diminished the result will be even more unfavourable, for then the complements will become first attached to all the unengaged amboceptors and only the remainder will be available for effective bactericidal action. Consequently in certain circumstances too much bactericidal serum may do more harm than good. Even if sufficient complement be introduced with the bactericidal serum it may lead to the formation of anti-complement and so, although a suitable complement as such will usually be present in the immune serum used for curative purposes, it may become engaged with the anti-complement and so be rendered useless. On the other hand, in active immunisation, although so far as we know there is no increased production of complement, that already existing in the organism will fit and activate the amboceptors formed during the immunising process.

To give a concrete example. Pigeons infected with vibrio Metchnikovi cannot be saved by the injection of the inactivated (heated) serum of rabbits immunised against the vibrio, unless some fresh rabbit's serum (containing complement) be added. The pigeon's blood possesses no suitable complement for the rabbit's amboceptors. On the other hand, by active immunisation of pigeons with dead culture of vibrio Metchnikovi they are soon rendered able to stand a multiple of the lethal dose, so that their blood must contain a suitable complement for their own amboceptors. For these reasons the treatment of enterica by weak immunisation with dead culture (Petruschky) may sometimes be more effectual, even after infection, than a bactericidal serum, or, perhaps, in spite of apparent theoretical objections, a combination of modes of treatment may be useful.

in man, or at least a bacteriolysin the amboceptor of which finds in human serum an appropriate complement. The latter condition will be the more readily fulfilled the nearer the species employed in the immunisation process is to man. Perhaps the non-success which as yet has attended the employment of typhoid and cholera serum will be converted identity of the precipitins formed in each case. In spite of this close relationship attempts to produce diseases like scarlet fever and measles have failed. It is true that on one occasion after swabbing out the throat with a swab from the throat of a case of scarlet fever an exudative tonsillitis resulted and from the chimpanzee's throat the so called streptococcus scarlatinæ was isolated, but I do not think that the chimpanzee had scarlet fever. Apparently the chimpanzee's cells do not possess receptors for the poison of scarlet fever or measles.

---

[1] tures I. and II. were published in THE LANCET of March 21st and March 28th (p. 853), 1903, respectively.

Certain acquired habits are known to predispose towards disease—e.g., alcoholism to phthisis. Have we any material evidence to show in what the predisposition consists? The experiments of Abbott and Bergey have shown that the administration to rabbits of alcohol diminishes the serum complement of the blood, while others have shown that it renders the rabbits more susceptible to infection by pathogenic organisms. In the case of man, diminution in the amount of serum complement in the last stages of disease has been shown on several occasions and affords an explanation of terminal infections.

There may be an underlying current of rationalism in the practice of periodical venesection in times gone by. The abstraction of protective bodies ought in the healthy organism to stimulate their reproduction and their overproduction. In some animals there seems to be a seasonal variation in the bactericidal power of the blood; who knows but this may be so in man too, and that by instinct our forefathers may have fallen on the most appropriate season? The question admits of experimental solution and a comparatively simple investigation would give the answer.

This line of thought suggests another mode of treatment based on Ehrlich's theory. Since infection is not possible in the absence of suitable receptors it might be feasible to devise some means of destroying these particular receptors. The method in our present state of knowledge would not be free from danger, for we might unwittingly destroy also nutritive receptors and do more damage than good to the patient. Perhaps it will form a part of the therapy of the future.

An organ has sometimes to protect itself against the action of a part of itself. We have already seen that bacteria are not digested in the alimentary canal and it is a familiar fact that ascarides can survive the digestive juices and it has recently been shown that the body wall of ascaris contains an anti-enzyme to pepsin. But what is more important and interesting is the fact that the human stomach wall contains an anti-enzyme to its own ferment. It is an obvious deduction to infer that a diminution in quantity of this anti-pepsin may have an ætiological relation to gastric ulcer. By the production of an anti-antipeptic serum an experimental verification of this inference would be possible.

SERUM DIAGNOSIS.

The existence of the agglutinins was one of the earliest results of modern investigations into immunity. They form a valuable means of identifying bacterial species and recognising the degree of relationship between various species, whilst they have also been employed practically as a diagnostic sign in disease.[2] So much has been written and said about them in the past seven years that it is hardly necessary to enter into a detailed description of their characters and production. I may mention, in passing, that the most recent work shows their probable identity with the precipitins but not with the amboceptors, since a serum can be produced, after suitable treatment, by the bacillus pyocyaneus which possesses immunising but not agglutinating properties.

But in the practical application of serum diagnosis various phenomena may occur which must be known and understood in estimating the value of the results. In spite of early warnings, some at once pinned their faith on the supposed infallibility of the test and then, finding that it was unable always to determine an uncertain diagnosis, became unbelievers. The agglutinins, although not identical with the amboceptors, nevertheless go roughly together with them in their rate and conditions of production in ordinary circumstances. Consequently in very severe infections, when all the cells are hard hit and many of them succumb, the agglutinin may either be used up or not formed, so that it is but natural for the reaction to be feeble or absent until the patient is already on the road to recovery. On the other hand, in mild attacks, which may be the result of either milder infections or of greater resistance, the reaction may naturally appear sooner and be stronger. Or, again, its absence may be due to an error in diagnosis. Finally, it may be the result of faulty technique.

The following points are worthy of consideration. Agglutinins may become converted into agglutinoids. These would in this form also unite with the bacilli like the complementoids with the amboceptors, but without producing any specific effect; no agglutination would take place. The bacilli may lose their agglutinability, although retaining the power of uniting with the agglutinin—viz., their agglutinable substance loses its functional atom-group. This group is comparatively unstable, so that unsuitable culture media, &c., may make the bacilli non-agglutinable, although uniting with the agglutinin. If the serum contain both agglutinins and agglutinoids and the latter have the greater affinity for the bacteria, even if present in less quantity, they may inhibit agglutination until the serum is so far diluted as to give the agglutinins a greater chance. This explains an early observation of my own for which I was then quite unable to account—that a higher dilution would sometimes agglutinate when a lower one would not.

The agglutinable substance is partly soluble in NaCl solution, so that an emulsion of bacilli should always be made fresh or the reaction becomes less sensitive

PARTIAL AGGLUTININS.

This expression is used to indicate the fact that several agglutinins may exist in a serum and may have slightly different cytophile groups, so that they will react differently as regards intensity with different strains of the same bacillus. Some may even act on nearly allied bacilli. Consequently it is a matter of importance what culture is used for serum diagnosis. It is also important in using an agglutinative serum both for the identification of a bacillus and for a serum diagnosis that the serum should be diluted as much as possible consistent with obvious action, since in this way the misleading action of the less numerous agglutinins is eliminated.

The serum reaction is also likely to be absent in cases of erroneous diagnosis. If bacteria are otherwise nearly allied it is, at any rate, possible that they may produce symptoms having much clinical resemblance. This seems to be so in typho-coloid fever on the other hand. The relationship between the bacteria may be so close that the patient's serum may act on each in comparatively low dilutions and the various strains may be separable only by degrees of dilution. Of course, discretion and reason must be exercised in all these cases, so that serum diagnosis requires not only considerable technical knowledge and skill but also an acquaintance with the clinical features of the case under investigation. It is only a symptom and its value as such in any particular case will vary like the value of any other symptom.

There is a strange gap in our knowledge of ætiology regarding those diseases of which one attack produces a very lasting immunity; of small-pox, typhus fever, scarlet fever, measles, and others we do not know the morbific germ. It is a curious coincidence that these diseases happen to be the most infectious. I believe that the discovery of their causes would throw great light on the phenomena of immunity. Even with our present knowledge I think we can assert that they are cases of mixed infection in which streptococci play a part, but only the minor part, as often in tubercle and diphtheria. Streptococcus scarlatinæ seems to occur pretty constantly in the throat and in the blood of scarlet fever patients. In two cases of measles I have found in the heart blood at the necropsy a streptococcus which is always present in the throats of patients suffering from measles. But to my mind it is pretty certain that these are only accessory causes. For we know that immunity to streptococcal infection is short and that second attacks are common. Many people exposed to scarlet fever infection get sore-throats repeatedly but not scarlet fever, and streptococcus scarlatinæ has been isolated from such cases.

The infectious fevers form an attractive theme for theorising and a yet more attractive objective for investigation. Their infectivity does not seem to be all of one [illegible] Thus yellow fever, an attack of w[illegible] confers immunity, has until quite recently [illegible] as infectious. Yet the infection is certainly not by contagion; it is transmitted by the mosquito. The pathogenic micro-organism has not yet been found. Can it be that the infectious diseases of temperate climates are transmitted in a similar fashion? It seems possible, but unlikely.

---

[2] First performed by myself on March 14th, 1896 and first mentioned by Gruber at the Wiesbaden Congress in April, 1896. The first publication, by Widal, was on June 26th, 1896, but he has not consented to give the date on which he performed his first serum diagnosis, so that it is presumably after mine, and after Gruber's utterance.

Even so, we are not any nearer either the cause of the disease or the reason for the long immunity. But I believe that the discoverer of the cause will find with it the key to *the innermost temple of the Theory of Immunity.*

FURTHER OBSERVATIONS ON THE TREATMENT OF SMALL-POX BY THE SERUM OF IMMUNISED HEIFERS.

BY R. S. THOMSON, M.D., D.SC., F.F.P.S. GLASG., F.R.S. EDIN.,
PROFESSOR OF MEDICINE IN ANDERSON'S COLLEGE MEDICAL SCHOOL AND VISITING PHYSICIAN TO THE CITY OF GLASGOW SMALL-POX HOSPITAL, BELVIDERE;

AND

JOHN BROWNLEE, M.A., M.D. GLASG., D.P.H. CAMB.,
PHYSICIAN SUPERINTENDENT TO THE CITY OF GLASGOW FEVER AND SMALL-POX HOSPITALS, BELVIDERE.

IN 1897 some observations on the treatment of small-pox by the subcutaneous injection of serum obtained from heifers immune to vaccinia were reported.[1] None of the cases were seemingly in any way affected by the treatment and it was suggested in that communication that possibly the administration of larger doses might be attended with more satisfactory results.[2] The presence of small-pox in Glasgow during the past two years has afforded an opportunity for a renewal of these observations and we propose to publish an account of 13 cases in which large doses of serum were administered.

The serum was obtained, through the courtesy of Messrs. Parke, Davis, and Co., from the vaccine establishment of that firm in Detroit and it was provided in bottles each containing 16 ounces. It was not concentrated or interfered with in any way except that tricresol had been added at the time of bottling in the proportion of 0·4 per cent. The sterilisation of this serum w[illegible] for some was kept in the City [illegible] at Belvidere for nine months [illegible] of decomposition, as proved [illegible] culture media inoculated w[illegible] administered by means of a metal syringe holding two ounces and were delivered into the subcutaneous tissues, generally in the axillary region. The dose varied to some extent with the age of the patient, but in adults the average amount given was 30 ounces of serum. Usually 16 ounces were injected as soon as possible after the patient was admitted and in most cases a like amount some hours later.

The cases selected for treatment were mostly of the severest type, the object being to avoid as far as possible the fallacy which arises from the modified course followed by small-pox in vaccinated persons who still retain a certain degree of insusceptibility. Had circumstances permitted only unvaccinated persons would have been selected, but as the number of these was small and the supply of serum limited it was thought better to treat severe cases as admitted, although vaccinated in childhood. Another circumstance which limited the number of suitable cases was the importance of using the serum only when the patient was admitted during the early period of the eruption—that is to say, as soon as the nature of the disease could be recognised with certainty. Of the 13 cases chosen 12 were undoubtedly small-pox, while the thirteenth, as will be seen later, was presumably not a case of small-pox, though its exact nature cannot be defined. Of the small-pox cases three were hæmorrhagic, four presented a confluent eruption on the face, while in five the eruption was very abundant but discrete. Five of the patients died.

It has been thought advisable to give a somewhat detailed report of the course of each case, so that the whole evidence upon which the conclusions are based shall be brought under the notice of the reader. For convenience the cases are arranged in three groups—the hæmorrhagic cases, the confluent cases, and those cases in which the eruption on the face was very abundant but discrete.

HÆMORRHAGIC CASES.

CASE 1.—A man, aged 35 years, was admitted into the City of Glasgow Small-pox Hospital at Belvidere on May 23rd, 1901, when the temperature was 102° F., the pulse was 65, and the respirations were 22 per minute. There was one primary, non-foveated, and glazed vaccination scar on the right arm measuring 0·27 square inch in area. The present illness began on the 20th with headache, backache, and general febrile symptoms. The eruption was first noticed on the 22nd. On admission three varieties of eruption were observed: (1) a sparse papular rash on the face, the arms, the trunk, and the legs, of fairly equal distribution; (2) a "petechioid" prodromal eruption over the groins and inner sides of the thighs extending over the flanks towards the axillæ; and (3) a hæmorrhagic [illegible] few true petechiæ distributed on [illegible] thigh in the trochanteric region, [illegible] hæmorrhage was present on the outer side of the right leg above the ankle. A few other hæmorrhages of a small size were found on the inner aspect of the left thigh. No petechiæ were seen on the face, arms, or trunk. The patient stated that he had spit a little blood on the day prior to admission and this hæmoptysis still continued. The physiognomy so frequently seen in cases of hæmorrhagic small-pox was present, the pupils were contracted, and the conjunctivæ were suffused, and a dusky flush was present on the face. The pulse was slow, regular, and full, and numbered 65 per minute. There was no complication in the internal organs.

The administration of serum was begun at 4 P.M. on the day of admission. 30 ounces were injected into the tissues of the right axillary region in two portions of 15 ounces each with an interval of two hours between the doses. The patient did not feel any discomfort or pain during the progress of the injection. Immediately thereafter the temperature was 101°, the pulse was 76, and the respirations were 30 per minute but the temperature rose steadily till at midnight it registered 104°. At this time the pulse was 94 per minute. Absorption of the serum was still incomplete 18 hours after the injection, a fluctuating swelling being present in the right axillary region. There was no sign of local reaction around the seat of puncture. No fresh petechiæ had developed, but the "petechioid" eruption in the groins and round the flanks was more decided. The urine contained a trace of albumin but no blood. During the day the patient had some hæmoptysis. On the 25th the temperature continued between 103° and 105° in spite of frequent cold sponging, the latter temperature being registered at 3 A.M. The pulse-rate varied between 100 and 120, but the rhythm was regular although the tension was low. The papular eruption had developed greatly and was fairly profuse on the face, the arms, and the back. On the back, and to a less extent on the arms, hæmorrhage had taken place into the bases of the papules. There was a fairly profuse petechial eruption most marked over the flanks and groins, but scattered petechiæ were also present on the abdomen and back. Around the puncture through which the serum had been injected a purplish-black area had appeared, circular in shape, with a diameter of five inches, and extending up into the axilla. No blood was expectorated on this day. The urine still contained some albumin, but no blood was detected in it or in the motions, although the bowels had been freely moved by medicine. Towards evening the patient became slightly delirious but answered questions intelligently, and as midnight approached the temperature rose to 106°, but fell during the night till at noon of the 26th it was 102·8°. The true small-pox eruption had now become vesicular and the petechial rash was more pronounced. The hæmorrhagic area round the puncture had slightly increased in size and become indurated. The pulse continued good with a rate of from 100 to 120 per minute. On the 27th there was no distinct change noted in the patient's condition, the temperature remaining between

---

[1] Scottish Medical and Surgical Journal, August, 1897.

[2] It was only after the publication of the above paper that the authors became aware of the experiments of M. A. Béclère, in which large doses of serum were employed in the treatment of small pox. (Note sur la Sérum thérapie de la Variole, par M. A. Béclère, Nancy, 1897.

102° and 104°, but the pulse was now much weaker and sometimes ran into a mere thread. On this morning a little blood was detected in the urine for the first time. The patch of hæmorrhage around the puncture was larger. On the 28th the eruption had become fully vesicular and the temperature continued high, but the pulse was of better tension and numbered 102. There was again a trace of blood in the urine. On the 29th the pulse had become very irregular. Subsultus was present. The temperature rose steadily from 101° in the early morning and reached 105° at noon. During the following nine hours it fluctuated slightly and was 103° at 9 P.M.; thereafter it rose to 106 4°, which it reached on the morning of the 30th, when the patient *died.*

CASE 2.—A woman, aged 40 years, was admitted into the hospital on June 30th, 1901, at 3 45 P.M. on the fifth day of her illness. The attack had been ushered in by the usual febrile symptoms, among which headache, pain in the back, and vomiting were the most prominent. The eruption had appeared on the 29th. On admission the temperature was 101° F., the pulse was 60, and the respirations were 34 per minute. The facial expression was that commonly seen in hæmorrhagic small-pox, the face being flushed and apathetic, the pupils contracted, and the eyes suffused. Under the ocular conjunctiva of the right eye there was a hæmorrhage of considerable size. The trunk and extremities presented a fading dusky scarlatiniform prodromal eruption, while a prodromal rash of "petechioid" spots was present in the groin and over the lower part of the abdomen. In addition to these several small true hæmorrhages were present over the lower part of the abdomen and on the legs. The true small-pox eruption was badly developed, but the forehead presented the characteristic velvety feeling sometimes noted when the early papular eruption is confluent. This eruption was scanty on the trunk and limbs. The pulse was small, soft, and slow. The patient had one primary, non-foveated, and glazed vaccination scar having an area of 0·27 square inch.

After admission the patient vomited persistently till 8 P.M., when an injection of 17 ounces of serum was administered hypodermically in the right axillary region. After the injection the vomiting continued. The vomited matter and the urine passed from the time of admission were free from blood, but the latter contained a trace of albumin. About 11 A.M. on the day after admission a second injection of serum was attempted, but as the patient began to vomit and showed signs of great uneasiness only nine ounces were administered. After the first injection the temperature fell slightly from 99·8° to 99°, at which it continued till 6 A.M. on July 1st, when it began to rise, reaching 100·4° at 9 A.M. After the second injection it continued to rise and reached its maximum of 102 6° at 3 P.M. The pulse seemed little, if at all, affected by the first injection, but about two hours later it increased in frequency and reached 108 immediately before death which took place at 8 P.M. on the day after admission. Prior to death the characteristic small-pox papules had become more numerous and a considerable eruption of small hæmorrhagic spots had appeared over the trunk and limbs, being especially abundant over the lower part of the abdomen and the inner side of the thighs

CASE 3.—A man, aged 20 years, was admitted into the hospital on May 11th, 1901, when he stated that he had been ill for three days. Though feeling a little out of sorts for some time before the onset of his illness it was only early on the 9th that his symptoms became really violent. An eruption appeared on the 10th. On admission the temperature was 104° F., the pulse was 124, and the respirations were 32 per minute. The patient complained of sore throat and was apparently very ill. The eruption consisted of a livid erythematous rash covering the whole trunk and extremities, while scattered over the skin were a considerable number of petechiæ rather more abundant on the chest and legs than elsewhere. The subconjunctival tissue was the seat of extensive hæmorrhage, so that the conjunctivæ were elevated beyond the corneal level. During the first few hours after admission the patient spat up a considerable quantity of blood and passed a motion which was almost black in colour from the presence of altered blood. There was very little true eruption on any part of the body. The throat was vividly congested and presented a number of papules. The patient presented two vaccination scars having a combined area of 0·9 square inch. These were not foveated and were slightly depressed but moderately well defined.

Between 11 P.M. and 1 A.M. on the following day 16 ounces of serum were injected into the connective tissue of abdominal wall. The injection did not seem to cause discomfort or pain. Immediately after the injection temperature fell, but rose again to 102°, at which it approximately till the patient's death at 2 P.M. on May Prior to death the appearance of the skin was very There was an almost entire absence of the variolous rash, the skin being of a deep dusky red set with very numerous hæmorrhages varying in size that of a pin's point to that of a split pea or greater.

Little can be said in criticism of the three cases. All were of the severest type of hæmorrhagic pox—a type which almost invariably ends fatally and where no known treatment seems to exercise any influence on issue. In the first case 32 ounces of serum were administered, in the second 26 ounces, and in the third 16 ounces. The longest course was that followed by Case 1, in which the true small-pox eruption reached well into the vesicular stage, so that apparently no modifying influence was exercised by the serum either upon the course of the true eruption or upon the hæmorrhagic condition. this case the seat of injection became the centre of a large ecchymotic spot which on examination post mortem was found to be the result of an extravasation of blood into the subcutaneous and muscular tissues of the pectoral region. Though the vaccination in this particular group of cases has little bearing upon the results of treatment it may be worth noting that all were vaccinated.

CONFLUENT CASES.

CASE 4.—A boy, aged 10 years, was admitted into the hospital on June 29th, 1901. The illness began on the [illegible] with headache, nausea, and vomiting. The eruption was first seen on the day of admission. The patient was said to have been vaccinated in infancy but no mark could be detected and consequently his vaccination must be regarded as *doubtful.* An unsuccessful attempt to vaccinate him had been made the day prior to admission. The temperature when first seen was 101·2° F. but rose shortly thereafter to 104°, when the pulse was 100 and the respirations were [illegible] per minute. There was an abundant eruption of early small-pox papules on the face, though elsewhere it was less abundant and was not so fully papular. There was also a faint macular erythema over the trunk and lower limbs. The internal organs were healthy on physical examination.

At 3 P.M. on the 29th six ounces of serum were injected into the right axillary region. The temperature rose thereafter and reached 105° at 9 P.M. On the 30th the patient received a second injection consisting of 12 ounces of serum at 11.15 A.M., after which the temperature fell to 99° at 3 P.M. but rose again to 103·6° at 6 P.M. During the night the eruption had developed and was now very abundant on the forehead and face, moderately so on the arms and legs, but scanty on the trunk. It was still papular. On the morning of July 1st the temperature was 99·2° but rose gradually during the day. The pulse was not so good. The bulk of the eruption continued papular but signs of vesiculation were observed here and there. On the 2nd the eruption had become vesicular and semi-confluent on the face which had swollen considerably, while it was still sparse on the trunk. The pulse had improved. From this date till that of the patient's death on the [illegible] the eruption passed through an uninterrupted and unmodified course of development, being fully pustular and septic at the time of death which took place on the thirteenth day of his illness. The temperature was somewhat irregular but showed on the whole an upward tendency, as is so commonly seen in cases of septic small-pox; coincidently the pulse-rate increased in frequency while the tension gradually fell. In this case there was no local reaction around the seat of puncture and no hæmorrhage occurred in the tissues into which the injection was made.

CASE 5.—A man, aged 37 years, was admitted into the hospital on Feb. 3rd, 1902, with a doubtful history. On admission the temperature was 102·8° F., the pulse was 114, and the respirations were 24 per minute. The eruption was very abundant over the whole body and was in an early papular stage. It promised to be confluent on the where its presence was associated with a consi amount of congestion. Over the rest of the body papules were arranged in somewhat corymbose the distribution of the patches being apparently by a cutaneous syphilitic eruption of a scaly The papules were abundant on the palms and soles.

fauces and palate were congested and were set with a very abundant rash which extended over the whole of the hard as well as the soft palate. There was one vaccination cicatrix measuring 0·37 square inch, which was non-foveated and ill defined.

Shortly after admission 16 ounces of serum were injected into the subcutaneous tissue of the right axilla and on the following morning a second dose of 16 ounces was injected into the left side. After the first injection the temperature fell to 99° but rose again on the evening of the following day, when it reached 101·9°. On this day the eruption had advanced considerably and was more abundant than on admission and the corymbose arrangement was more striking. The patient complained of no discomfort or pain resulting from the injection. All the serum had been absorbed and there was no evidence of a local reaction. The rash now became fully vesicular and pustulation was noticed on the face on the 9th. From this time onwards the usual course was followed by the eruption, though crusting began rather earlier over the syphilitic patches than on the surrounding skin. The eruption was septic. Throughout the patient's condition was regarded as unsatisfactory, but it became grave on the 12th, when some redness and induration were noticed over the right pectoral region. A patch of cellulitis was observed over the point of the left elbow also and another over the sacrum. The cellulitis over the right pectoral region was treated surgically, but the patient gradually sank and died on the 20th. Before death the temperature rose to 106° and the pulse to 152.

CASE 6.—A man, aged 22 years, was admitted into the hospital on Jan. 28th, 1901, on the fourth day of his illness. This commenced with pain in the head and back and general symptoms of fever. The rash appeared on the day of admission. On admission the temperature was 99·2° F., the pulse was 76, and the respirations were 26 per minute. The eruption was very abundant on the face, the back, the arms, and the thighs, and was in an early papular stage. On the scalp it was sparse and there was none below the knees or on the palms or soles. The fauces and palate were congested and thickly set with papules which extended forward as far as the teeth. Over the lower part of the back the remains of a prodromal erythema were visible. The pulse was small and easily compressible. The heart sounds were feeble.

At midnight 16 ounces of serum were injected subcutaneously and at 2.30 A.M. a second injection of a like amount was administered, but the temperature seemed little influenced. On the 29th the eruption was more abundant, having extended over the legs, the soles, and the palms. Indications of vesiculation were present in a few of the elements on the arms and buttocks. There were no indications of local reaction at the seat of puncture. From the 29th onwards the eruption over the face and trunk developed regularly and the elements which were small and irregular had become fully pustular by Feb. 2nd and on the following day began to dry in. The secondary fever was slight and ended on the tenth day of the illness.

CASE 7.—A woman, aged 36 years, was admitted into the hospital on May 15th, 1901. The history was somewhat indefinite, but it seemed clear that the eruption was first noticed on the 12th. The earlier symptoms consisted of headache, sickness, and those of general fever. The eruption over the face and the greater part of the body was in the early vesicular stage. On the face it was confluent and abundant and evenly distributed on other parts of the body. The temperature was 101° F. The vaccination was doubtful.

At 11 P.M. on the day of admission 16 ounces of serum were injected into the subcutaneous tissue of the right axilla. The temperature at the time of administration was 101° and this fell towards morning to 100°. In the morning the patient declared that she felt much better, but her pulse was somewhat rapid, being 124 per minute. The whole of the serum had been absorbed and there was no evidence of a local reaction. The eruption, which was more decidedly vesicular than on the previous day, felt very dry, as is so frequently the case with eruptions which ultimately run a modified course. It should be stated that this character of the eruption was present, though in a less degree, before the serum was administered. On the 17th there was commencing pustulation on the face and on the 19th the eruption in this situation was commencing to crust, while on other parts of the body pustules were still present. On the 20th the temperature fell to normal and did not rise again. Convalescence was uninterrupted.

In regard to this group of cases the following points may be noticed. In all the dose of serum administered was considerable. In two of them 32 ounces of serum were injected subcutaneously; in one, a boy, 18 ounces were given, while in the fourth case owing to the modified course followed by the eruption only 16 ounces were administered. There was no evidence of local reaction in any of the cases. In Case 5, however, it is open to discussion whether the cellulitis might not have resulted from the injection of the serum. In this connexion it should be observed that the case was exceedingly septic from the maturation of the pustules onwards; that the first patch of cellulitis commenced at some distance from the seat of puncture and made its first appearance on the tenth day after the serum had been injected and that a similar condition appeared a little later over the left elbow and over the sacrum—that is to say, a long distance from the first puncture; and, lastly, that the patient was the subject of late secondary syphilis.

As to the course followed by the confluent cases, as has been already said, two proved fatal, in one of which the vaccination was doubtful while in the other the area of vaccinal scarring measured 0·37 square inch. The former of these patients died on the thirteenth day of illness and the latter on the twenty-third and in both the eruption ran an unmodified course from begining to end. Of the two cases where recovery ensued, in one (Case 7) the vaccination was doubtful while in the other (Case 6) there were four scars with an aggregate area of 0·66 square inch, three-quarters of which was foveated, yet in spite of the apparent differences as regards vaccination both ran a somewhat similar course. In both cases desiccation commenced on the tenth day from the first appearance of symptoms and in both the temperature fell to normal with the first appearance of drying in. This course as seen in Case 6 is that commonly enough observed in persons suffering from small-pox who still enjoy a certain degree of protection derived from their original vaccination. The doubtful character of the vaccination, however, in Case 7 raises the question as to whether the modified course followed by the [illegible] been the result of the serum, [illegible] ceived only 16 ounces and that because on the day after the injection the dryness and general character of the eruption seemed to indicate that it was about to follow an abortive course, or, in other words, the physical conditions of the rash suggested that the patient possibly enjoyed a certain degree of immunity the result of vaccination performed in infancy of which no local evidence could be discovered. The abundance of the eruption on the arms during the acute stage of the attack and the changes in the skin present thereafter while the patient was under observation made the certain detection of vaccination scars of small size practically impossible.

CASES IN WHICH THE ERUPTION ON THE FACE WAS VERY ABUNDANT BUT DISCRETE

CASE 8.—A man, aged 48 years, was admitted into the hospital on Feb. 21st, 1902. His illness began on the 17th with general febrile symptoms, but of these none was especially prominent. The eruption was first noticed on the 20th. The patient's temperature on admission was 101·6° F., the pulse was 80, and the respirations were 24 per minute. There were two foveated vaccination scars on the left arm, with a combined area of 1·12 square inches and with well-defined margin [illegible] present on the [illegible] rash on the [illegible] was moderately abundant on the soles and the palms. This eruption had all the physical characters of an early papular small-pox rash which gave promise of becoming very abundant. The patient complained of soreness in the throat and this on examination proved to be congested and set with a number of small papules. There was nothing to be found in the internal organs on physical examination.

About four hours after admission the patient received an injection of 16 ounces of serum into the subcutaneous tissue of the left axilla and about an hour later a second injection of a similar amount was made into the left flank. After the injections the temperature fell and reached normal in the early morning. At this time an examination of the urine revealed the presence of a trace of albumin. During the following day the temperature rose and reached 102° at midnight, but towards morning it fell again to 99·8°. An examination of the sites of injection showed a little swelling in both situations with some pain and tenderness.

that if we are to judge by the alleged influence of immunising serum in preventing the full development of vaccination in susceptible animals, in both of these cases there was ample time for the manifestation of any such action which might be possessed by the serum to show itself.[3]

The other seven cases ran a more or less modified course, with the exception of one of the less severe cases in which the attack was practically unmodified, crusting commencing on the face on the twelfth day of illness. In this case the serum was administered on the ninth day before crusting commenced, so that there was presumably sufficient time for the immunising action of the serum to show itself. In the other patients the eruption ran a distinctly modified course, showing that some protective influence was present in each case, but whether this influence was furnished by a primary vaccination or by the injection of the immunising serum is not easy to say.

Of these six cases, five were undoubtedly vaccinated, while in one the vaccination was doubtful. In the former the area of vaccinal scar varied between 0·44 square inch and two square inches, but in only two was foveation present. The ages varied between 17 and 48 years. It is impossible to assess the precise degree of protection enjoyed by these patients as the result of their original vaccination, but the extent of the eruption and the date at which desiccation commenced showed that this was by no means great. It is likewise impossible to determine whether the less severe course followed by these cases and the rapid desiccation of the eruption, sometimes without crusting, are to be attributed to the action of the serum, but judging from he result of experiments upon the immunising action serum from vaccinated heifers when injected into eifers prior to vaccination it is probable that in ost of the cases under discussion the serum was dministered sufficiently early to influence the course the disease if it was capable of doing so. Some ght may be thrown upon this point by consideration f Case 13. In this case 19 ounces of serum were injected 3 hours, and an additional 12 ounces 24 hours, prior to accination, yet in spite of this large dose of immunising rum the revaccination was successful and ran the usual ourse. This observation is probably unique and shows that n amount of serum equal to 1 in 75 of the patient's weight as unable to bring about any change in the course commonly followed by revaccination. This patient almost certinly did not suffer from small-pox, and this opinion is ased upon the course followed by the eruption, which was uite unlike that seen even in the most modified cases of that disease, and in addition the patient was successfully revaccinated—a fact which is strongly in favour of the opinion just given, for though it is possible to vaccinate an individual during even the last day of the incubation period in some cases, and even during the prodromal stage, the local reaction being often marked and running quite a normal course, yet vaccination performed after the first appearance of the rash has, in the experience of the City of Glasgow Small-pox Hospital, invariably proved negative. In this connexion it may be stated that while during the past ten years about 250 persons have been vaccinated at various dates after the appearance of the eruption yet the operation proved unsuccessful in every case. In a few, papules of about the size of a small split-pea appeared having characters unlike those usually seen in the papule caused by vaccination. In others a slight reddening of the vaccinated area with increased prominence of the cutaneous papillæ resulted, but in the great majority no local reaction which could be ascribed to vaccination occurred, nor in any instance was there any suggestion of the development of a papule into a vesicle.

An analysis of the different cases cited here shows the following:—1. No action of any kind was observed in the hæmorrhagic cases treated with serum. In Cases 1 and 2 as the serum was administered only 24 hours before death there was probably too little time for it to exercise any influence; but in Case 3, where the patient died a week after the injection, there was probably sufficient time for the influence of an immunising agent to become apparent had the serum contained such a substance in sufficient amount. 2. In certain cases in which the serum was administered from eight to 18 days before death or commencing desiccation, no influence whatever seemed to be exercised upon the course of the disease, though in these there was ample time for the serum to act. 3. In the remaining six cases the serum was administered from four to seven days before desiccation commenced. In all of these the course was modified and there was probably sufficient time for the serum to exercise an immunising influence, but as all, with two exceptions, were undoubtedly vaccinated, and as these two were probably vaccinated, it is impossible to determine whether the modified course resulted from the primary vaccination or from the treatment. 4. Case 13 shows that the serum completely failed to modify the course of a revaccination. 5. It is possible that the eruption which appeared on the eighth day after the serum was administered may have been due to the presence in the serum of some agent identical with, or closely resembling, substances present in the blood of variolous patients. 6. That the serum in Case 13 did exercise some influence upon the tissues, though none so far as could be determined on the vaccination, is suggested by the development of the cutaneous erythema on the eighth day after the administration of serum was begun. Details of this eruption and of its distribution have already been given, but we may observe here that the characters and distribution were precisely those so frequently present in the erythematous and some other of the prodromal eruptions so *commonly found in variola and varicella and exceptionally* after vaccination. This suggests that some active body may be present in the serum in sufficient quantity to produce a distinct reaction in the absence of variola—that is to say, when the individual has not been immunised by passing through the earlier stage of small-pox against the toxins presumably present in the serum.

Though not directly bearing on the treatment of small-pox by serum it may not be out of place to add a few remarks regarding the special sequelæ which may attend the administration of large doses of serum in plague and in diphtheria. The prevalence of these diseases during the last few years has afforded exceptional opportunities for acquiring experience in the use of serum in large doses. During the last outbreak of plague in Glasgow some of the patients had as much as ten ounces of anti-plague serum administered either hypodermically or by the intravenous method, while in a number of cases of diphtheria where death seemed impending anti-diphtheritic serum to the amount of four ounces was given through the same channels. Anti-plague and anti-diphtheritic serum are both derived from the horse and their administration is frequently followed by a marked reaction in which fever with articular pains and cutaneous eruptions of an erythematous and urticarial character are prominent features. The severity of this reaction bears apparently no relationship to the amount administered, being often very severe where minimal doses are given and absent in many cases where the dose administered is large. The action of anti-variolous serum differs markedly from that just referred to, as it only once, in our experience, was followed by any reaction which could be directly attributed to it. This experience is in agreement with that of M. Béclère[4] who found that the serum of heifers is much less toxic when administered to man than that of horses, but the frequency with which, according to M. Béclère, cutaneous eruptions followed on the administration of anti-variolous serum is contrary to our experience—a fact which suggests that the serum used by us may possibly have contained fewer toxic substances than that employed by that observer.

Glasgow.

ETHYL CHLORIDE AS A GENERAL ANÆSTHETIC.

By W. J. McCARDIE, B.A., M.B., B.C. CANTAB.,
ANÆSTHETIST TO THE GENERAL HOSPITAL, BIRMINGHAM, ETC.

IN 1848 Heyfelder successfully used ethyl chloride as a general anæsthetic in the human subject. Benjamin Ward Richardson[1] also found it to be a good anæsthetic. He placed a pigeon in a chamber and diffused the vapour of the chloride through the chamber. He says: "The density of the vapour, taking hydrogen as unity, is 32·25. The period for producing narcotism with this vapour is of necessity prolonged and the vapour requires to be pushed freely and vigorously into the chamber or it will produce little more than excitement. The excitement is rather great, but in a minute or two the animal succumbs. The breathing is short and oppressed and the anæsthesia is not deep. During recovery there will possibly be some convulsive action." Ethyl chloride was tried as a general anæsthetic in animals by a committee of the British Medical Association.[2] This committee found that it quickly caused convulsions and stoppage of respiration so that its employment was denounced. Little more was heard of it till in 1895 and 1896 Carlson and Thiesing observed that in certain cases where the drug was used locally general anæsthesia was produced. Thiesing actually tried the effect of the drug on himself and others. Then Billeter and other dentists advocated its employment as a general anæsthetic in dental work. Lotheisen[3] of Innsbruck, *seeing in a German journal that Soulier* of Lyons had used ethyl chloride as a general anæsthetic, tried it himself. Soulier, however, did not use ethyl chloride, but another similar drug, ethylidene chloride. Soon a goodly number of cases of ethyl chloride narcosis were recorded by Lotheisen, Ludwig, and Wiesener, and since 1898 ethyl chloride has been employed in many thousands of cases. Seitz[4] of Konstanz collected up to the end of last April 16,000 cases of narcosis carried out throughout the world, of which I gathered for him 525 in England. In these cases there was one death, that of a very unfavourable subject.[5] Since April some thousands of other cases have been recorded, among them being another fatal case, also in a bad subject. The patient was a child, aged one year and nine months. The operation was tracheotomy for diphtheria. The patient died suddenly about three minutes after the beginning of the operation. Post mortem nothing beyond the usual pathological appearances of diphtheria was found except an enlarged thymus gland. Death in this case was due to heart failure and the ethyl chloride may not have been the principal factor in the fatality.[6]

[4] Note sur la Sérum-thérapie de la Variole, par M. A. Béclère, Nancy, 1897.

[1] Medical Times and Gazette, Dec. 28th, 1867.

Seitz, comparing the death-rate of ethyl chloride with that of other anæsthetics, gives the following figures:—pental, 1 in 200; chloroform, 1 in 3000; ether, 1 in 5000; ethyl bromide, 1 in 8000; and ethyl chloride, 1 in 16,000. Thus it would appear that, according to Seitz, the safest anæsthetic is ethyl chloride, with the exception of nitrous oxide, in which, of course, the death-rate might be put at 1 in many hundreds of thousands. However, perhaps it is not quite fair to compare ethyl chloride, which has only been used, say, some 25,000 or 30,000 times, with drugs which have been administered many scores and hundreds of thousands of times. I may remark that nitrous oxide is little used on the continent and that chloroform being the commonly used anæsthetic surgeons are always on the look-out for some quickly narcotising drug the action of which speedily passes over and which may be used for short operations. Ethyl bromide has in recent years been very much used, but its death-rate has been set at 22 in about 120,000 cases. This is probably too high a reckoning but it is certain that at least 22 deaths have taken place during, though perhaps not always from, ethyl bromide anæsthesia. Ethyl chloride seems to be quickly growing in favour abroad.

Physico-chemical characters.—The chemical formula is C_2H_5Cl. It is a colourless liquid of aromatic odour and has a sweetish taste. Its density is 0·92 at 0° C. The density of its vapour, taking air as unity, is 2·3 and its boiling point is 12·5° C. It volatilises at ordinary temperatures without residue. It is very combustible and burns with a green flame, setting free hydrochloric acid. As usually put up, in tubes, it does not show a tendency to decompose. I have used ethyl chloride which has been in stock for 18 months.

Physiological action.—Owing to its great volatility ethyl chloride is very quickly absorbed and almost as quickly eliminated. This is a great point in favour of safety. Wood and Cerna found that ethyl chloride caused augmentation of the respiratory movements and lowering of the blood pressure during narcosis, with immediate return to the normal state. The pulsations of the heart decreased in frequency at first and were increased towards the end of the administration. Seitz found from sphygmographic observation that the arterial pressure was rather raised during narcosis, while the vascular tone and cardiac action were stimulated. Koenig experimented on a dog, a rabbit, and a monkey. He *found that the rapidity of narcosis depended on* the degree of dilution of ethyl chloride with air. A *mixture of 1 in 10 of air* caused narcosis at the end of *six or seven minutes.* In equal parts narcosis was complete in *some seconds* and lasted *for several minutes.* In the dog the arterial pressure was slightly lowered. If ethyl chloride were used without any admixture *of air the lowering* of arterial pressure was regular and very *rapid, ending in stoppage* of the respiration and heart beats. In the monkey much the same effects were observed. "During *complete* narcosis," says Koenig, "the vagus nerve became inexcitable." Koenig's experience on the arterial depression agrees *with the* results of Malherbe and Roubinovitch[7] obtained in man by means of the sphygmo-manometer of Potain. In 24 cases cited by these authors arterial tension was lowered 22 times. In a general fashion the number of arterial pulsations varied directly as the degree *of arterial* tension, diminishing duri[illegible]
returning to the original r
vations they found in all
in one case of intermittent bigeminal pulsations during narcosis. Most authors have asserted that there are no changes in the urine after administration, but the two just quoted found biliary pigment and traces of albumin, indicating slight affection of the cells of the liver and kidneys. Such manifestations, however, were quite transitory. These, and other more serious changes, by the way, occur after chloroform and ether narcosis. Seitz says that the respiratory centre is affected before the cardiac apparatus, thus giving time for effective resuscitative *measures.*

From personal experience, during administration, I have not been able to satisfy myself that arterial tension, as a rule, is lowered, but have found that the pulse during deep narcosis sometimes becomes rather slower than normal and usually preserves its regularity. Respiration, however, is markedly stimulated, both in frequency and depth, during deep anæsthesia. The colour is improved, because of vaso-dilatation, which often leads to sweating, and, as I have once recorded in THE LANCET,[8] a well-marked rash, like the ordinary ether rash, has appeared over the upper part of the body. Considering the vascular flushing and stimulation of respiration I cannot imagine that, any more than is the case with alcohol, there can be any dangerous degree of circulatory depression while these exist; and, as a matter of fact, just as in the administration of ether, so long as respiration is forcible and colour is good I pay little or no attention to the frequency or quality of the pulse, even in a patient sitting upright for a dental operation.

With regard to the type of patient, children as a rule take ethyl chloride very well and quietly. Adults also very quickly pass under its influence. Any trouble during induction occurs usually with hysterical people, drinkers, smokers, and strong men. In most cases excitement varies directly as the quantity of air admitted during the induction of anæsthesia. The accounts of excitement recorded during induction and the failures to cause anæsthesia are in almost every case due to too much mingling of air with the vapour. It has been found that in Russia, where the patients are great consumers of exciting drinks, especially alcohol, tea, and coffee, excitement is much more common than in other countries where less of these liquids is taken. Seitz in 310 cases only twice found a state of excitement and then in alcoholics. The resulting tonic spasm of the extremities was so great as to make operation impossible. According to Blank of Kieff immoderate tea-drinking more predisposes to excitement than alcohol and coffee specially tends to cause vomiting.

Course of the narcosis.—A great many different statements as to the rapidity of action of ethyl chloride have been made, but from a perusal of all the literature that I can find it is apparent that the rapidity of induction of anæsthesia and the amount of excitement depend altogether on the degree of exclusion of air. In my earliest cases, recorded in THE LANCET,[9] I used Breuer's mask which admitted a fairly large amount of air along with the vapour and did not allow re-breathing. Then considering that certain cases of excitement and one or two failures altogether to induce anæsthesia were due to the too great dilution of the vapour with air in this inhaler, I, as I had previously suggested in a short article on ethyl chloride in THE LANCET,[10] began to administer from an Ormsby's ether inhaler, since when in more than 350 cases I have only once met with a marked degree of mental or muscular excitement during narcosis and that was in the case of a young man who had just been drinking whisky freely. The excitement, however, in his case was not uncontrollable. It is a great thing, I think, to say of any anæsthetic that in so many cases only one instance of excitement has been met with. Of course in the case of children there is occasionally struggling from fear during the first few breaths. Since using this inhaler I have found the induction of anæsthesia to be wonderfully speedy. I find the most useful form of Ormsby's inhaler is that devised by Hewitt as it contains a removeable water chamber which can be heated in hot water and, lying against the sponge, prevents it from freezing, as it is liable to do when ether or ethyl chloride is used. The tubes of ethyl chloride are graduated in cubic centimetres, hold 60 thereof, and have a larger spraying capacity than usual. I have mostly used kelene or Henning's æther chloratus pro narcosi, but am now also administering a preparation made for me by Messrs. Duncan, Flockhart, and Co. in Edinburgh. This has given very good results, is more agreeable, and, I believe, purer than kelene. The vapour of ethyl chloride is by no means disagreeable. I have had it myself and have found its subjective effects are as nearly as possible like those of nitrous oxide. Taking it one day from a Clover's inhaler consciousness disappeared in 20 breaths, and when next I looked at the clock I noticed that five minutes had elapsed. Personally, I have not suffered any after-effects. It is by some patients preferred to nitrous oxide. In certain cases this may be because I have given ethyl chloride by Ormsby's inhaler, through which, of course, respiration is perfectly free, while in certain old-fashioned forms of gas apparatus the airway is rather narrow and a sense of choking or suffocation may be brought about. The nervous patient, moreover, breathes much more easily through an Ormsby's inhaler than any other form of gas apparatus. Certain it is that the vapour of ethyl chloride if given in proper doses of from three to five cubic centimetres from an Ormsby's inhaler or any other is not unpleasant and is not irritating to the mucous membranes, nor does it cause a feeling of suffocation. Some administrators have used small cones made of nonporous material and others many folded compresses fitting closely over the face to administer ethyl chloride, thus as far as possible excluding air and possibly introducing an asphyxial element. It has been remarked that the struggling, which is not uncommonly associated with complete exclusion of air, is in itself liable to produce syncope. Again, such apparatus as a cone of paper or cloth must be pressed so firmly on to a patient's face as sometimes seriously to disturb him. The full-sized Ormsby's inhaler will hold about two full breaths of air when distended and when applied in the ordinary way probably already contains the amount of one full breath of air. If to this be added the amount of one expiration when the bag is applied it contains practically two full breaths of air, minus, of course, the 4 per cent. of oxygen which has been absorbed into the lungs during the last breath. Since 20 per cent., roughly speaking, of the air breathed consist of oxygen, and supposing that at each breath 4 per cent. are absorbed there remains in the bag enough oxygen for nine full breaths or thereabouts before there need be any lack of oxygen in the lungs, but as the breathing during induction is usually lighter than normal the time taken to absorb this quantity of oxygen is often much greater, and before the time that all the oxygen in the residual and supplemental air is used up full anæsthesia, as a matter of fact, is found to exist.

[7] Ma [illegible]

In the larger number of my cases ethyl chloride has been given for the removal of adenoids and tonsils or for dental extractions, and it will be of interest to know the time taken during induction of anæsthesia and the duration of anæsthesia after the removal of the mask. In some of these instances, where the operation was not expected to be severe, I have only induced light anæsthesia—that is, have allowed retention of the conjunctival reflex; but in most cases deep narcosis has been induced—that is, as shown by soft snoring or stertor, loss of conjunctival or corneal reflexes, lax muscles, usually rather dilated pupils, and eyeballs turned downwards and inwards. By the way, it may be remarked that the size of the pupil is much greater during early deep anæsthesia with ethyl chloride than is the case with other anæsthetics of which I have had experience. In a long case the pupil contracts after the first few minutes. So far as I can judge dilated pupil is generally coincident with deep anæsthesia, in the early stages at any rate. Anæsthesia, in free-breathing patients, seems to occur as quickly in the case of children as in adults. The single dose which I use with an Ormsby inhaler is generally about three cubic centimetres for a child and from five to seven cubic centimetres for an adult, sprayed on in one dose. Reapplication of the inhaler in certain of the dental cases resulted in a very much longer anæsthesia than the first.

In all cases where anæsthesia is not induced in less than one or one and a quarter minutes, or at the very most one and a half minutes, the reason is that air is being admitted to the inhaler or else not enough ethyl chloride is supplied. Since I have used Ormsby's inhaler I have never failed to induce anæsthesia, though in one or two cases it has been too short, and then the reason has been that I have not sprayed enough on. When using Breuer's inhaler I once or twice absolutely failed to induce anæsthesia and had to change to chloroform. Those administrators who use cones and compresses not infrequently confess to failures. I have not failed to anæsthetise alcoholics deeply with the Ormsby inhaler.

For continuation of anæsthesia I spray on two or three cubic centimetres every two or three minutes and allow air at fairly frequent intervals, according to the state of the patient; in fact, I give the drug much as I should ether, only, of course, less freely. Sometimes, to preserve full muscular relaxation one must abolish the conjunctival—or even corneal—reflex, especially for the first five or ten minutes; on the other hand, one may sometimes work throughout an operation with a brisk conjunctival reflex. The induction period is often startling in its rapidity if the breathing be free and deep, and I have known a patient to lose consciousness and not to flinch at a skin incision after six full breaths of ethyl chloride, or in 20 seconds.

I subjoin in tabular form the average figures of a number of cases taken from my note-books.

KELENE.

Single dose, from three to eight cubic centimetres, Ormsby's inhaler.

77 Dental Cases.

Average duration of induction, 50·9 seconds.	Average duration of anæsthesia, 71·3 seconds.
Longest case of induction, 2½ minutes (a fault in administration).	Longest case of anæsthesia, 2½ minutes.
Shortest case of induction, 20 seconds.	Shortest case of anæsthesia, 3 seconds.

197 Adenoid or Adenoid and Tonsil Cases.

Average duration of induction, 51·9 seconds.	Average duration of anæsthesia, 64·64 seconds.
Longest case of induction, 2 minutes 10 seconds.	Longest case of anæsthesia, 2 minutes 30 seconds.
Shortest case of induction, 15 seconds.	Shortest case of anæsthesia, 20 seconds.

Dental and Throat Cases.

Averages up to Dec. 9th, 1902.

Average duration of induction, 51·4 seconds.	Average duration of anæsthesia, 67·97 seconds.
The youngest patient, 11 months old, suffered from adenoids, and after 30 seconds' inhalation was anæsthetic for one and a half minutes.	

Let us now compare the times taken in dental cases to produce deep anæsthesia by nitrous oxide, and the duration of that anæsthesia, with those of ethyl chloride. According to Hewitt, the average inhalation period of nitrous oxide is 55·9 seconds and the available anæsthesia is 30 seconds. Thus the induction period with ethyl chloride is shorter by five seconds, while the available anæsthesia is longer by 41 seconds. As compared with "gas" and oxygen, Hewitt states that the average period of administration is 110·5 seconds. Thus ethyl chloride has the advantage by 59·6 seconds. The average available period of anæsthesia by "gas" and oxygen is 44 seconds, which is exceeded in the case of ethyl chloride by 27·3 seconds. In these comparisons it must be remembered that my averages include both cases of light and deep anæsthesia. If I were to take average figures of the cases only in which I induced deep anæsthesia, the advantage would be much greater for ethyl chloride. In series of cases of removal of adenoids and tonsils at the Ear and Throat Hospital, it has been found, using ethyl chloride as the routine anæsthetic, that in an hour more than 12 cases can be operated on—e.g., 10 in 45 minutes and even six in 20 minutes, making a total for one morning 16 in 65 minutes. The posture I prefer for these cases is the recumbent one, the head being on a level with the body—that is, without a pillow under it, while the foot of the table is raised about 12 inches by means of blocks. In this position there is very much less tendency for blood to get into the larynx than in the horizontal posture and I do not think that the bleeding is seriously increased. Jansen's modification of Doyen's gag, previously inserted unopened, saves time afterwards in the case of children especially, though it is easy to put in a Mason's gag after removal of the inhaler.

---

[10] THE LANCET, July 20th, 1901, p. 123.

With regard to the use of ethyl chloride for these operations, the general opinion of operators in this city who have had experience of it seems to be favourable. Mr. F. Marsh[11] in his recent Ingleby lectures says that "on the average about two minutes of anæsthesia and analgesia was obtained in 20 of his cases and that its advantages over 'gas' are the longer time given and the absence of congestion and cyanosis. Recovery from its influence is quite as rapid and the patients are able to walk back to bed. No troublesome after-effects occurred in my cases." It has been claimed for ethyl chloride that the condition of analgesia persists for an appreciable time after apparent return of consciousness. This condition, as far as I can judge, lasts after short operations for about from a quarter to half a minute or so after apparent return of consciousness and is much more marked than in the case of nitrous oxide.

It has been said that with ethyl chloride it is impossible often to obtain full muscular relaxation and hence the uselessness of the drug for reduction of fractures and other opera- [illegible] 'hat, with [illegible] flaccid, [illegible] for a few minutes afterwards and in one case of operation on the foot I could not secure full muscular relaxation until a lapse of about eight minutes. The same thing occasionally happens with ether. I have had no chance of administering for the reduction of a dislocation and should be glad of one.

With regard to the after-effects the only ones that I have observed are headache and sickness and perhaps one very doubtful case of syncope. Headache is not very common and in my longest case, 26 minutes, was only slight, and lasted for about half a day. Sickness is decidedly more common and persistent than it is after nitrous oxide. Many patients, particularly if unprepared, vomit once on coming round. It has been claimed by some foreign observers that the after-effect of ethyl chloride narcosis is usually a feeling of well-being and even of hunger. The patients are able to eat within one hour or two hours after an ordinary administration. During recovery, particularly after short operations, the patient is rather more "fuddled" than after nitrous oxide, and any injudicious noise, talking, or restraint may lead sometimes to excitement, rarely forcible, for a minute. Marshall, in some 50 cases, noted two charges of indecent assault brought by patients as the noteworthy after-effect. Vomiting has only been severe in four of my cases. In the first one, a woman, aged 67 years, who had an aural polypus removed, vomiting did not begin till six hours after the operation, but it continued for 12 hours. The second patient was a delicate, nervous girl, to whom I gave ethyl chloride for an operation on the os calcis, lasting nine minutes. Afterwards she vomited at frequent intervals for 30 hours until she was given some albumin water, which, I am told, often lessens or stops post-anæsthetic sickness. This patient some months afterwards had ether, preceded by a little chloroform, for a second operation, and was again just as sick. On yet another occasion there was severe vomiting after another anæsthetic. In this case, then, it would seem that there was exceptional nervous or stomachic sensibility. In a third case, that of a boy, aged 13 years, who, after proper preparation, was anæsthetised for two minutes during operation on the foot, after-sickness and vomiting lasted for 24 hours. He was given chloroform on another occasion and was then just as sick. The fourth patient, a youth, aged 17 years, was given ethyl chloride, after the usual preparation, during four minutes for tenotomy and movement of the foot. He was sick for 12 hours. It is certain, I think, that the tendency to after-vomiting is much less than is the case with chloroform and ether, but is distinctly greater than with nitrous oxide.

With regard to the danger of ethyl chloride I have little to say, because I have seen none directly associated with it. There has been no such thing as syncope, respiratory or cardiac. The only difficulties which I have seen have been in mouth operations and were due to obstructions to respiration from blood in the throat or falling back of the tongue and were overcome by simple mechanical means. Cases of asphyxia and syncope have been described abroad.

Lately there has been used in France and advocated in this country by Dr. Rolland of Bordeaux a compound preparation called "somnoform." It is composed of 60 parts of chloride of ethyl, 35 parts of chloride of methyl, and 5 parts of bromide of ethyl. Its composition was decided by theoretical considerations, with a view to secure simplicity, rapidity of action, and elimination and safety. It is claimed that the diffusibility of methyl chloride, which evaporates at – 23° C., tends to quickness of action, while the chloride of ethyl prolongs anæsthesia and the ethyl bromide causes an after-analgesic state. I have tried this mixture in 11 cases and could find in its action no practical difference from that of ethyl chloride. My chief objection to it is that the ethyl bromide causes an unpleasant garlicky smell which pervades the room and also subjectively persists in the patient for one or two days afterwards.

Ethyl chloride would appear to be particularly advantageous in many short operations lasting up to ten or 15 minutes. Fromaget recommends it as preferable to chloroform in eye work, especially in paracentesis, iridectomy, peritomy, tenotomy, muscular advancement, enucleation, &c., and is particularly pleased with his results for operations on children. It has been used in gynæcological and obstetric [illegible] I have ac [illegible] on the tit [illegible] 68 years), 18 minutes; for circumcisions, from five to ten minutes; for drainage of the knee-joint, ten minutes; for mammary adenomata and cysts, several cases; for enucleation of the eye, four cases; for strabismus operations, several cases; in an operation on an old sinus from the kidney, 18 minutes; and for excision of hydrocele, 11½ minutes. In the last case anæsthesia was induced in half a minute and was as good as with ether or chloroform. The patient recovered consciousness in from one and a half to two minutes after cessation of the administration, and the only after-effect was slight headache for a time. One hour after the operation he had pudding and milk for dinner. Thus, the advantage here, as compared with ether or chloroform, was probably very great. I should like to recount my rough notes on the longest case.

The patient was a woman, aged 26 years. The operation was on tuberculous bone in the foot. The patient was thin and dreadfully nervous, had a quick pulse, was of good colour, and had some cough. Nothing abnormal was found in the heart. The ethyl chloride was administered first in the anæsthetic room, from seven to eight cubic centimetres being sprayed on to an Ormsby's inhaler. Anæsthesia occurred in three-quarters of a minute. The patient was then wheeled into the theatre. Two or three cubic centimetres were sprayed on to the inhaler at intervals during the operation. During the cleansing of the foot light anæsthesia was kept up, the conjunctival reflex being brisk and the legs and arms being rigid. Then at the commencement of the operation deeper anæsthesia was induced, the conjunctival and corneal reflexes being abolished, the pupils moderately enlarged, the legs, arms, and fingers still rigid, and the latter flexed; there was no movement. Between the eighth and ninth minutes the limbs relaxed, the pupils contracted, [illegible] increased. Some frothy mucus was secreted and came from the mouth. As time went on lighter anæsthesia was used, slight phonation and the conjunctival reflex being allowed. Throughout the operation the face was flushed as if ether was being used. The administration lasted for 25 minutes, [illegible] the drug were used. Full [illegible] inute after the removal of [illegible] d as she was sent away on the ambulance and in the ward once vomited some frothy mucus. Afterwards there was no nausea or vomiting. In the afternoon she felt rather drowsy and complained of some frontal headache the rest of the day but slept well at night.

In dental work I have several times found ethyl chloride of the very greatest advantage—for example, in the following cases.

---

[11] Marsh: THE LANCET, June 21st, 1902, p. 1751.

A big strong policeman came to have two or three teeth removed. One of the other anæsthetists at the Dental Hospital had previously tried to administer nitrous oxide. He just got the patient under but no more; the man came round before anything could be done. He was brought to see me. Having had one or two previous unsuccessful experiences of policemen as subjects for nitrous oxide I did not care to try it again, and as the usual alternative anæsthetic would have been nitrous oxide followed by ether, by no means a short or pleasant interruption in a busy morning at the Dental Hospital, more particularly as the patient was unprepared and wished to get back to duty soon, I decided to give him ethyl chloride. I put six or seven cubic centimetres on the Ormsby inhaler and after inhaling for one minute without a trace of excitement he was very deeply anæsthetised—i.e., his colour was heightened, his breathing was stertorous, the eyeballs were turned down, the pupils were enlarged, the conjunctival and corneal reflexes were absent, and the limbs and jaws were lax. Anæsthesia lasted more than one and a half minutes. The patient quietly recovered in another minute and in two or three more walked out of the room.

To take another case. A short, thickly built, heavy-jowled man of middle age, with thick and fat tissues about his neck and jaws, probably a beer-drinker, came into the anæsthetic room at the Dental Hospital suffering from a large dental abscess and marked trismus. By the way, it is important to remember in this type of patient that just as their tissues are outside so they are inside—that is to say, the tissues inside the mouth, naso-pharynx, and airway are fatty and thickened, thus narrowing the air passages. Again, the abscess bulged largely into his mouth, still more narrowing its cavity. Any congestion, cyanosis, or increased spasm caused by nitrous oxide would entail serious difficulty and danger during administration. Similarly, the increased circulation, congestion, mucus, rapid breathing, and spasm which ether would set up would tend to cause dangerous trouble with the respiration. In such a case, therefore, chloroform usually would be the chosen anæsthetic. Administration would be by no means a pleasant or an easy task in this unprepared patient. Having put a very small prop between the teeth, I gave him ethyl chloride, with a result almost exactly the same as in the last case. During the deep anæsthesia the jaw muscles became relaxed, Mason's gag was introduced, and not only the tooth causing the abscess but half a dozen others were deliberately removed during an anæsthesia of from one and a half to two minutes. There was no excitement or after-effect at all.

Yet another recent case. I was asked to give prolonged "gas" by Paterson's apparatus to a female patient for the extraction of eight or ten teeth. She had nasal obstruction and could breathe through the nose only slightly. I managed to get her under but could not keep her so, so she came round without anything having been done and was very much upset by the non-success. It is a great mistake, I think, in these cases to allow the patient to leave thinking that she cannot take an anæsthetic, because she would be fearful another time and believe that the administration was impossible or dangerous, so I proposed to give her ethyl chloride at once. She took it perfectly. We had a long anæsthesia of one and a half minutes, during which the operator did more than he originally proposed to do, and the patient recovered very well, though afterwards she suffered from some degree of shock, due largely, I think, to the previous failure.

There does not seem to be any more than one contra-indication to the administration of ethyl chloride. In marked narrowing about the larynx chloroform is better as being less stimulative. Patients with heart, lung, and kidney disease seem to take it well. In the case of children ethyl chloride is a perfect anæsthetic for small operations, such as opening abscesses, taking out teeth, especially the extraction of four six-year-old molars in a crowded mouth, and the removal of adenoids or tonsils. It is safe and rapid in its action and recovery in them is usually without after-effect, especially if they are properly prepared. It is practically impossible to give "gas" satisfactorily for any operation lasting more than a quarter of a minute in the mouth of small children. Not only do they become cyanosed and bleed so much that it is almost impossible to see what one is trying to do, but convulsion of the limbs and body is very awkward and recovery is exceedingly rapid. With ethyl chloride, however, there are none of these disadvantages.

Abroad, ethyl chloride is increasingly used in the so-called "mixed" anæsthesia—i.e., as preliminary to chloroformisation just as in England "gas" is often given before ether. Malherbe,[12] who has had an experience of 700 cases of ethyl chloride narcosis, says that by this method ethyl chloride suppresses the dangers of primary syncope under chloroform. Again, it much lessens shock and the quantity of chloroform used and also diminishes subsequent gastric troubles. I have often given ethyl chloride before ether and have had as good and often much better results than by the preliminary administration of "gas," but I have not used it as a forerunner of chloroform.

I have not tried ethyl chloride for the largest operations because I see no advantage in it over ether or chloroform, for one is working within narrow limits because of the tendency to quick return of consciousness. I do not think that very quick recovery (in one or two minutes) after big operations is an advantage to the patient, who would too often awake to the consciousness of acute pain, mental distress and shock, apart from the fact that his immediate surroundings and removal to bed would be, to say the least, most unpleasant. However, abroad, hernial, renal, and other operations have been done under ethyl chloride administered for well over an hour in the longest cases. It is well to recognise that all narcotic drugs have limitations, and ethyl chloride certainly has them, if one is to do the best for one's patient. I think, with many foreign observers, that it is well suited for many short operations lasting up to 15 or 20 minutes. Especially for short throat operations by skilled and quick operators, and for certain dental cases, is ethyl chloride of great advantage. As compared with ethyl bromide, which is much used abroad instead of "gas," ethyl chloride is safer because, as Binz says, the bromine compounds have a much more lasting and toxic effect on the tissues than the chlorine compounds. According to Overton[13] narcosis with chlorine derivatives can be kept up much longer than is the case with bromine compounds. This probably depends on the fact that watery solutions of bromine compounds gradually split up and give off free bromine. Certainly the death-rate is much less in ethyl chloride than in ethyl bromide. Again, ethyl bromide leaves behind it a garlicky smell and taste which persist in the patient's breath for one or two days after. The drug, too, is very liable to become impure on keeping.

In conclusion, with regard to the first and all-important question of safety, what I can say is that, having given ethyl chloride 450 times, I have never had any trouble during narcosis ascribable to the drug itself. I give it now with confidence and out of a total of more than 1000 cases last year of administrations in general, as apart from dental, surgery I have administered it about 350 times. I should judge that any serious effects would be seen first in the respiratory apparatus and secondarily in the heart. The general action on the circulation and respiration appears to be stimulative.

PS.—Since this paper was written I have brought up my total of administrations to more than 620 and have had little further noteworthy to record except that I administered it to a patient for removal of adenoids and tonsils immediately after recovery from fainting. The ethyl chloride greatly improved the colour and respiration, but just at the end of the administration, in order to be on the safe side, I added a dose of ether to the Ormsby's inhaler. I have lately been using ethyl chloride containing about 7 per cent. of methyl chloride. This addition probably has some advantage in quickening evaporation and carrying off ethyl chloride vapour. In regard to ethyl chloride in dental work, it is not to be preferred to nitrous oxide for routine use. It is of advantage in cases where the prolonged methods of administration are not available or the conditions are such as I have described in the cases related above. In dental work the passing over from ethyl chloride narcosis to that of ether is much quicker and easier than from that of nitrous oxide. If one and a half minutes' anæsthesia is not enough for the operator, an ounce of ether should be poured into the Ormsby's inhaler, which is quickly applied, and full narcosis will occur in two or three minutes. By giving a full dose of the drug one can always be sure of one and a half minutes' anæsthesia. By reason of the portability of the apparatus and the quickness of the phases of narcosis, ethyl chloride when administered from an Ormsby's inhaler is an ideal anæsthetic for short operations in country practice.

ON SOME

OPERATIONS FOR RECTIFYING CROOKED AND DEPRESSED NOSES.[1]

BY W. J. WALSHAM, F.R.C.S. ENG.,

SURGEON TO, AND LECTURER ON SURGERY IN THE MEDICAL SCHOOL OF, ST. BARTHOLOMEW'S HOSPITAL.

DURING the last 20 years I have had under observation a very large number of various external deformities of the nose. Some of the operations which I have devised and performed for their correction have not, as far as I know, been brought prominently before the notice of the profession.

FORCIBLE STRAIGHTENING.

In THE LANCET of August 29th, 1891, p. 492, I described a nasal forceps that Messrs. Arnold and Sons had made for me for seizing the nasal bones and twisting them forcibly into position, but these can only be safely employed in recent or comparatively recent cases. When the injury is of long standing and the bones have become consolidated in the deformed position so much force is necessary to move them that there is a risk of severe laceration of the mucous membrane and tearing of the skin. Some further procedure is then usually necessary to allow of satisfactory replacement. In many of these cases of crooked nose it will be found that the deformity is not the result of a fracture of the nasal bones but of their bodily displacement at the fronto-nasal suture. On looking at the patient from the front this may not at first sight be evident, as the anterior or cartilaginous portion of the nose is generally at the same time deflected in the opposite direction, a slight protrusion occurring at the spot where the cartilages join the nasal bones. This protrusion frequently leads the patient to imagine that a fracture has occurred here. On examining the patient from above and behind it is seen clearly that the nasal bones are bent to one or other side at their junction with the frontal bone and at the same time slightly rotated on their long axis so that whilst the surface of one bone looks more upwards than normal the other one looks less upwards than normal. It will also be obvious that the slight protrusion above spoken of is caused by the angle of bending where the cartilages spring from the bones. On the side opposite the protrusion a corresponding slight depression will be found to exist. The deflection of the bones is frequently overlooked by those whose attention is [illegible] se, which points in [illegible] interior of the no[illegible] to be deflected. For such cases forcible straightening is generally insufficient, but I have succeeded in many by supplementing the straightening by a subcutaneous osteotomy along the naso maxillary suture.

SUBCUTANEOUS OSTEOTOMY ALONG THE NASO-MAXILLARY SUTURE.

An incision, varying in length from an eighth to a quarter of an inch, is made through the skin along the course of the naso-maxillary suture down to the bone. Through this incision a small chisel, such as is used in mastoidectomy, is introduced and carried by a few taps with a mallet through the bone, care being taken not to puncture the mucous membrane. The bone incision is then prolonged sufficiently up and down along the course of the suture to detach the nasal bone from the nasal process of the superior maxilla, the chisel is withdrawn, and the small skin puncture is temporarily closed by a pad of aseptic gauze. The opposite nasal bone is then detached in a similar way. A stitch of the finest fishing-gut may be used for drawing the edges of the skin puncture together and the wound is sealed by a collodion gauze dressing. The delicate linear scar is practically invisible in a few weeks. The bones can [illegible] either by the fingers or by t[illegible] replaced they will retain the [illegible] any special apparatus or may be steadied for a day or two by some form of light nasal truss.

A very good impromptu truss can be made by an ordinary pair of forceps and a roller bandage. A piece of rubber tube about half an inch long is slid over both blades of the forceps so as to compress their ends together—the amount of pressure to be exercised by the ends on the bones or cartilages being regulated by the distance the rubber ring is passed down over the forceps The blades, protected by rubber, are then placed one on each side of the nose over the nasal bones or cartilages. The pressure exercised by the rubber should be just sufficient to grasp the bones gently and to steady them in position. A pad of lint is next placed on the forehead just above the glabella to protect the skin and the forceps are bound down to this by a strip of adhesive strapping. Under the upper end of the forceps a second pad is placed of sufficient thickness to tilt the ends grasping the nasal bones downwards far enough to insure a good hold. The arrangement is next secured firmly in position by a roller bandage. It need not be worn for more than a day or two, as after the first few hours there is little fear of the bones becoming displaced, since consolidation takes place very rapidly.

A somewhat similar osteotomy I have found useful in diminishing the breadth of the flattened nose before resorting to the injection of paraffin for restoring the bridge, but in such cases some tying of the bones together by the subcutaneous suture or by wiring will generally be also required.

SUBCUTANEOUS SUTURE OF THE LATERAL NASAL CARTILAGES.

In slight degrees of depression of the cartilages the result of injury or disease the flattened bridge can be materially sharpened by this method. A straight needle armed with fine kangaroo tendon is passed through the skin and the depressed cartilages just below their junction with the nasal bones and brought out through the skin on the opposite side. A curved needle is now substituted for the straight one, introduced through the same puncture, carried about a quarter of an inch downwards between the skin and cartilage, and then made to perforate the skin. The straight needle is again employed to carry the suture through the second puncture and across the nose through the depressed cartilages and is brought out at a corresponding spot on the opposite side. A loop of suture is thus left on one side of the nose between the skin and corresponding cartilage By a similar manœuvre the suture is brought out through the first puncture. The suture is next drawn tight, bringing the cartilages together, and the knot is buried at the first puncture. In passing the suture the mucous membrane should not be perforated if it can possibly be avoided and care should be taken that no portion of the deeper layers of the skin is involved or some puckering of the skin at the seat of the puncture will be produced. The punctures are closed by collodion. In many cases a subcutaneous osteotomy of the nasal bones will be found necessary at the same time.

WIRING THE CARTILAGES TO THE NASAL BONES.

When the depression of the cartilages at their junction with the nasal bones is such that the ends of the nasal bones project under the skin subcutaneous suture will not as a rule be sufficient. For such I have obtained the happiest results by wiring the cartilages to the bones. An incision is made exactly in the centre of the nose in a vertical direction, [illegible] half an inch above the ends of the bones [illegible] inch or more over the cartilages. [illegible] are carefully dissected up from [illegible] a good half-inch on each side. With a sharp knife the cartilages are next divided transversely along the line of the osteo-cartilaginous junction, avoiding perforation of the mucous membrane. If the cartilages can now be brought up to the level of the bones well and good; if not the projecting ends of the bones may be snipped off with fine bone scissors The end of each bone is now perforated with a small bone-drill and a fine silver wire suture is passed through the hole thus made with a curved needle, which is then made to perforate the corresponding cartilage from within outwards On twisting the loop the cartilage will be drawn up into place. The opposite side is now treated in the same way, the ends of the wire are securely beaten down, and the external wound is closed with the finest fishing-gut sutures and sealed with a collodion gauze dressing. In this way I was recently successful in curing the most hideous deformity in a lady who had literally smashed her nose in a severe fall from a height. The ends of the nasal bones projected beneath the stretched and reddened skin and threatened to protrude (Fig. 1). The cartilages were depressed a good quarter of an inch below the level of the bones and their distal ends were tilted upwards so that the nostril looked almost directly forwards. The profile of the nose was so revolting that the patient could not venture out without wearing a thick veil. I performed the operation above described and succeeded in fixing the cartilages in an excellent position. A temporary suture having a subcutaneous loop on one side was passed through the cartilages and tied over a piece of rubber tube on the other for the purpose of drawing the cartilages together and so sharpening the bridge whilst consolidation was taking place. The wound healed by first intention. The temporary suture was removed on the fifth day and the result was so satisfactory (see Fig. 2) that the patient did not think it worth while to have the very slight depression that remained obliterated by the injection of paraffin. When last seen the parts had consolidated firmly without any sinking down of the nasal ridge.

After wiring.

INJECTION OF PARAFFIN SUBCUTANEOUSLY.

So much has been written of late on this subject that it need not be referred to further than to say that I have kept the cases on which I have thus operated under observation and have found that the improvement remains. The part filled with the paraffin has gradually hardened and the improved appearance of the nose continues as good as it was the day after the injection. I commenced this treatment just after the first account of it was made known in this country but have not published my cases as I wished to learn first how the method would stand the test of time. This is an important element in all cases of new methods of treatment; for instance, I know of several cases in which great improvement was accomplished by transplanting bone, inserting gold plates, &c., but the improvement was not maintained. The nose again fell in and in the case of the plates so much irritation was set up that they had ultimately to be removed.

SHIFTING THE SEPTUM BODILY AT ITS JUNCTION WITH THE FLOOR OF THE NOSE.

In some cases of crooked nose it will be found that the whole septum is fixed to the nasal floor out of the median line. This is perhaps more especially so in patients who have been the subject of complete hare-lip or who have undergone no operation, or an imperfect operation, for this deformity. In a patient, aged 15 years, on whom I operated a year or so ago an attempt had been made in infancy to cure the hare-lip but this had failed and nothing further had been done. When she came under my observation there was a very wide cleft of the lip on the left side extending through the alveolar process of the maxilla into the nose and the nasal septum was a quarter of an inch or so to the right of the middle line. Before closing the cleft in the lip I first turned back the right half of the lip, exposing the right nasal cavity as well as the left, and then with strong bone scissors I detached the maxillary crest from the floor of the nose. The septum could now be carried over to the left and was fixed in the middle line by sutures. In this way the nostrils were equalised and the nose was brought over to the straight in its anterior half. An osteotomy was at the same time necessary to correct the deflection of the nasal bones. Subsequently the gap in the lip was closed in the ordinary way and the shape of the nostril was improved by a plastic operation on the left ala and the patient after a prolonged stay in the hospital was discharged with a most satisfactory lip and nose. The improvement was very great. In another patient the hare lip had been fairly satisfactorily united in infancy, but the septum remained too much to the left and the nose in consequence projected to that side. Here I turned up the upper lip after the manner of Rouges's operation and having exposed the septum cut it with the maxillary crest from the maxillary bones with strong bone scissors. The whole septum with the anterior part of the nose could now be carried over to the right where it was easily held by a plug in the left nostril. As far as I know this method of transplating the bone of the septum has not been hitherto employed. Anyhow, I have not seen any account of it, but I would recommend it strongly to surgeons as a very desirable measure in similar cases.

FORMATION OF A SEPTUM FROM THE MAXILLARY CREST.

Where the whole septum has been destroyed as the result of ulceration together with the anterior part of the nose one of the difficulties to be contended with is to give firmness and rigidity to the restored organ, whether the flaps are taken from the forehead, cheeks, or arm. I remember many years ago an endeavour was made by my colleague, Sir Thomas Smith, to obtain this firmness by first transplanting a portion of the cartilage of the ear into the flap of skin it was subsequently intended to employ for the new nose. This, however, was before the days of antiseptics and the attempt unfortunately failed. I have recently manufactured a septum by turning up the maxillary crest. The patient had lost the whole of his septum and about a third of the anterior part of his nose, his nasal cavities thus being converted into a huge gaping chasm I made two parallel cuts through the mucous membrane down to the bone about half an inch apart along each side of the maxillary crest and as far back as I could reach, a cross cut uniting the parallel incisions. A small mastoid chisel was next introduced obliquely into each incision, the maxillary crest was detached from the underlying bone and bent forwards with the overlying mucous membrane which in front served as a hinge and carried to the detached bone its blood-supply. The septum thus made was attached above by temporary sutures to the remaining skin of the nose and further held in position until consolidation in the new portion was complete by a piece of rubber tube passed behind it with the ends of the tube fixed on the face. The bone remained in position, thus forming a new columella. Later I intend to restore the nose still further by transplanting a skin flap. Without the new septum this would have been flabby, unsupported, and liable in time to sink in, but I hope now this will ultimately form a very respectable nose. It seems to me there are many possibilities of restoring the septum from the maxillary crest or even from a piece, if necessary, of the whole thickness of the hard palate, and I have no doubt that further attempts will be made to utilise this bone. The case is not yet complete but bids fair to be a marked success.

Harley-street, W.

ON THE USE OF IODIPIN IN CASES OF UTERINE FIBROID.

BY JOHN A. SHAW-MACKENZIE, M.D. LOND.

IODIPIN is, as I understand, a combination of iodine and sesame oil. It has been introduced by Messrs. Merck of Darmstadt, it is said to be an efficient substitute for iodide of potassium generally, and, according to all accounts, it causes no disagreeable effects. Having long taken an interest in the medicinal treatment of uterine fibroids I am fully aware that good authorities have recommended iodide of potassium as producing at least amelioration of the symptoms and that Dr. Samuel Ashwell[1] and others in the past have recommended iodine as producing arrest of growth, diminution, and sometimes disappearance. I therefore wrote in November last to Messrs. Merck asking for special information as to the use of iodipin in uterine fibroid and menorrhagia, but was informed that so far as they knew it *had not been used in such conditions.* I have since had opportunities of treating two cases by the hypodermic method of administration and not having so far heard of or seen any reports of cases similarly treated I venture to record the following notes.

---

[1] Diseases of Women, 1845. On the Diminution and Disappearance of Uterine Tumours, THE LANCET, Feb. 18th, 1854, p. 180.

The first patient was under the care of Dr. John Shaw at the North-West London Hospital and I am much indebted to him for the help and opportunity which he gave me. She was 33 years of age and attended as an out-patient on Dec. 10th, 1902. A large, moveable, somewhat elastic tumour, presumably a fibroid, extended to an inch above the umbilicus and the abdominal wall was tightly stretched over it. On a *subsequent occasion the uterine sound* passed three and a half inches and the mass appeared to move with it. She had been married for five years but had never been pregnant and from the first this condition was excluded. Her father died early from pulmonary tuberculosis. Her mother and two sisters were stated to have suffered from fibroid. A small lump was first noticed by the patient two and a half years ago. She complained of constant loss of blood "all the month round," the first few days of the period being profuse. The os uteri and cervix were healthy and high up, the tumour itself being largely abdominal. *After explaining what treatment* was proposed, to which she readily consented, one cubic centimetre of iodipin (25 per cent. strength) was injected into the cellular tissue of the buttock. On the 17th, as there was still some loss of blood, two cubic centimetres were injected on the other side. On the 31st it was stated that there had been no hæmorrhage for a fortnight. Three cubic centimetres were injected, the injections being made alternately into either buttock. On Jan. 7th it was stated that there had been *no loss of blood for three weeks* and the tumour was found to be diminished to a finger's breadth below the umbilicus. On Jan. 21st she stated that the period began on the 7th and lasted for eight days, the first two days being free. The tumour was on this day well below the umbilicus. Five cubic centimetres were injected and after this date seven cubic centimetres were injected twice a week. On Jan. 28th a period began. The tumour was swollen and had risen to just below the umbilicus. On Feb. 11th there was obvious uniform reduction of the tumour; it felt softer and a sulcus could be felt at the fundus. On the 25th the tumour was again swollen to just below the umbilicus. Ten cubic centimetres of iodipin (10 per cent. strength) were injected and the injections were continued twice a week. On March 4th *she stated that a period began on the 1st* but was very slight; it lasted for six days. The tumour was again obviously reduced. On the 11th the tumour was again found to be swollen to within an inch of the umbilicus. On the 18th it was stated that a period began two days before but the loss was slight. The sulcus at the fundus was an inch below the umbilicus, but the two sides were nearly on a level with it. The tumour, however, seemed to be flatter and softer and the abdominal wall could be easily raised up from its surface. Ten cubic centimetres (25 per cent. strength) were injected.

The full dose of iodipin is stated to be ten cubic centimetres (25 per cent. strength) for ten days consecutively. No local or general inconvenience whatever has in this case *followed the injections which were given with due regard* to antiseptic precautions. All that, so far, can be said is that there has certainly been an improvement in the patient's general health and that th[illegible] though the maximum had not [illegible] fore the treatment was commenced. Pain was complained of at times but the patient was not laid up or much inconvenienced. It is agreed that there is no indication for operative interference and the treatment is to be continued a little longer.

The second patient was unmarried and under 40 years of age. When I was called to see her on Dec. 21st, 1902, she was in much pain which was referred to the left inguinal region. Her tongue was coated, her temperature was 101° F., and there was inability to retain food. The bowels were [illegible] several days. A large hard mass, [illegible] l reaching to an inch above the [illegible] *she was losing blood freely* and passing large clots. For some long time she had been laid up at the menstrual periods with profuse losses. Enemata were ordered and on the next morning the bowels had been relieved, her temperature was normal, and she expressed *herself as quite comfortable. On Dec. 30th, the period* being just over, Mr. Skene Keith kindly visited her with me. He diagnosed a freely moveable fibroid (with outgrowths) and extending well into the pelvis, but not fixed or pressing on the bowel. The cervix was small and healthy, with the tumour above moving with it and reaching to the level of the umbilicus. He agreed with me that there was no indication for operation and consented to a trial of iodipin being made. (I should mention that someone else had a few days before, and independently of me, *diagnosed* a large fibroid and had recommended its removal.) On Jan. 1st, 1903, I commenced injections of two cubic centimetres of *iodipin (25 per cent. strength) into the cellular tissue of the* buttock and continued injections daily for ten days on alternate sides, doubling the dose on the fifth day. As the first insertion of the needle caused pain, on subsequent occasions I first applied a piece of ice to the surface which proved perfectly satisfactory. On the 6th the tumour was two fingers' breadth below the umbilicus. A right lobe was now easily defined to the right of, and below, the umbilicus. Not knowing how much or how little might be expected of the iodipin I prescribed also teaspoonful doses of Gardner's syrup of hydriodic acid three times a day and four cubic *centimetres of iodipin were now injected. On the 8th the main* mass of the tumour had diminished astonishingly. A sulcus could be felt between it and a smaller lobe to the left. On the 10th the patient went out of town feeling very well. On the 19th she returned; the tumour was then swollen to about two fingers' breadth below the umbilicus and both lobes were enlarged. Six cubic centimetres of iodipin were injected and the injections were continued twice a week until March 10th. On Jan 20th the period commenced without notice or pain. The loss of blood on the first day was said to be free but without clots. Numerous superficial blue veins were perceptible over the buttocks and there were slight cough and hoarseness. The bowels also were troublesome. The insertion of the needle on this day drew a drop or two of blood *and all the previous punctures were congested* with slightly bruised areas. On the 23rd the patient said that she could hardly recollect having previously had such an easy time. She had no pain and no loss of blood worth mentioning. It ceased on the 25th. On the 27th Mr. Skene Keith kindly visited her again and reported that the tumour was less by one-third than at his previous visit and that it was quite two and a half inches from the umbilicus. There was no dropping into the pelvis to account for the diminution. On Feb. 7th the right lobe seemed to be quite an isolated small oval moveable tumour. The main mass could only be felt on deep palpation above the pubes. On Feb 21st a period began. The tumour was slightly swollen but less so than at the last period. The same local and general vaso-motor condition *was present. There were no pain and only a slight loss of* blood lasting four days, the patient going about all the time. On March 10th she went out of town and on the 17th she returned in excellent health. The tumour and the lobe could still be felt but deep palpation was required to make them out Six cubic centimetres of iodipin were injected. The patient is now going abroad for a time.

Hildebrandt[2] noted in his cases in which ergotin injections were used that the needle drew blood at the menstrual periods. Both these cases of his and this one of mine conform probably to those cases of vaso-motor origin noted by Strassmann and referred to by Dr. Thomas Wilson.[3] There was no cardiac complication in this case The case itself seems to be in marked contrast to the preceding one, in which there is no particular general periodical vaso-motor disturbance. Possibly iodine may influence the vaso-motor or trophic centres themselves, in addition to its presumable action on the muscle element and nutrient vessels No particular local or general inconvenience has followed the [illegible] agreeable effects often associated with the administration of iodide of potassium. An irritating dry patchy eczema appeared on Feb 25th, continuing more or less, and some darkish stains, lasting a day or two but disappearing without trouble, recently showed themselves. The treatment is a continuation of the older iodine one, only, as it seems to me, by a more convenient, rapid, and direct method of administration of the drug. It does not confine the patient to bed or the house, nor is there apparently any disagreeable effect. The cases are only two in number and sufficient time has not elapsed for forming a proper conclusion, but I publish them in the hope that others may be induced to put such a simple method to the test before resorting to operation.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF OPERATION FOR ACUTE HÆMATEMESIS.

BY ARTHUR H. BUCK, F.R.C.S. EDIN.,
ASSISTANT SURGEON TO THE SUSSEX COUNTY HOSPITAL.

As operations for acute hæmatemesis are still comparatively rare the following may be thought worth recording.

The patient, who was a woman, aged 39 years, had suffered from heaviness and fulness in the epigastrium after food off and on for six months. She had experienced nausea but was not sick. There was no history of melæna. Dr. F. Robson of Haywards Heath saw her first on Jan. 21st, 1903, when she had vomited one pint of blood and was collapsed. Adrenalin was administered by the mouth and rectal feeding was ordered. On the 22nd there were repeated attacks of hæmatemesis and much *melæna. Ergotinin and adrenalin* were given. On the 23rd further hæmatemesis took place and I saw the patient in the evening with Dr. Robson. Her condition was then one of collapse and she had lost over six pints of blood by measurement in two and a half days. After a consultation with Mr. G. C. Clarke of Lindfield and Dr. Robson an operation was agreed upon for the following reasons: (1) that it was not a proper thing in her condition to advise removal to the Sussex County Hospital; (2) that judging from the repeated attacks of hæmatemesis there was likely to be another; and (3) that to a patient already *in extremis* another attack was likely to prove fatal before assistance could be obtained. The difficulties of the situation were increased by the patient living in a cottage and by the only light being that of a paraffin lamp.

The stomach was opened by a vertical incision anteriorly, as no ulcer could be felt from outside, and the ulcer was found at the cardiac end on the posterior wall by sweeping the finger round the mucous membrane. It was brought into view with some difficulty and proved to be acute, with no thickening around the edges. The diseased area having been excised the aperture was closed posteriorly by a purse-string suture and one or two Lembert's sutures on the peritoneal aspect and anteriorly by a second purse-string suture in the mucous membrane. The anterior incision was closed with Lembert's sutures. Mr. Clarke administered the anæsthetic. The patient was put back to bed apparently no worse for the operation. Dr. Robson, who conducted the entire after-treatment, at first administered strychnine and saline injections and afterwards fairly large nutrient enemata were given, about two pints a day being absorbed. The services of an excellent nurse were obtained on the second day. On the thirteenth day—namely, three days after the first food had been given by the mouth—a somewhat severe attack of parotitis set in on the right side followed by one on the left side. Except during this attack and for some little time afterwards the temperature was normal. The patient, when seen on March 20th, was perfectly well in every way.

The following statistics are quoted from Mayo Robson and Moynihan's "Surgery of the Stomach": A series of 26 operations in acute cases showed 14 deaths and a series of 19 in chronic cases showed two deaths (Hunterian Lectures). A later series in America showed 13 deaths in 32 acute cases and six deaths in 31 chronic cases. Mr. B. G. A. Moynihan in a paper read before the Royal Medical and Chirurgical Society on Jan. 27th, 1903, and published in THE LANCET of Jan. 31st, p. 294, divides the cases of hæmatemesis into those the result of acute and those the result of chronic ulceration and says: "In hæmorrhage from an acute ulcer medical treatment alone will suffice, surgical measures will very rarely be necessary. If any operation has to be done gastro-enterostomy will probably prove to be the most effective. In chronic ulcer operation should be advised as early as possible." So far as my experience goes I should have said that it was hardly safe to be quite so dogmatic, as besides the above case I have recently come across a case where a girl with a chronic history suddenly died from profuse hæmorrhage from a chronic ulcer. Other cases of perforation have come under my observation where it was quite impossible from the history to say whether the ulcer was acute or chronic before operation. An operation for acute hæmatemesis, whether from an acute or chronic ulcer, seems to me to be an emergency operation in which one would not feel satisfied unless one performed that for which the operation was undertaken and secured the bleeding point. As to whether a gastro-enterostomy was advisable then or later would, I suppose, depend upon the condition of the patient at the time, both generally and locally, and upon the past history of dyspepsia.

Brighton.

A CASE OF IODOFORM POISONING.

BY ALAN H. MUIR, M.B., CH.B. GLASG.,
HOUSE SURGEON TO THE SWANSEA GENERAL HOSPITAL.

THE patient, a man, aged 35 years, was admitted to the Swansea General Hospital on March 5th, 1903, with a large non-tuberculous abscess on the calf and the thigh of the left leg. The temperature was 102° F., the pulse was 100, and the general condition was fair. On the 6th the temperature ranged from 98° to 99°. On the morning of the 7th I opened the abscess, irrigated the cavity, and put in a connecting drainage-tube. Whilst my assistant was putting in iodoform quite half an ounce or more dropped accidentally into the large cavity. For 24 hours the temperature remained normal. At 8 P.M. on the 8th the patient had a rigor, when the temperature rose to 102°, and two hours afterwards it was 104°, the pulse being 140 and weak and thready and the respirations being 24 and normal in character. The patient, who now became restless and delirious but remained conscious, vomited three or four times. Nothing noteworthy regarding the pupils, the urine, &c., was observed. Quinine and brandy were now administered and at 12 midnight when the temperature was 103° the cavity was washed and swabbed out, the iodoform forming quite a coat. In 12 hours the temperature, which had come down gradually, was normal, the pulse was 120 and fair, and the patient was quiet and sensible. This condition was maintained, the temperature remaining normal, the pulse being 80 and good, and the respirations being 24.

For permission to publish these notes I am indebted to Mr. W. F. Brook, senior surgeon to the Swansea General Hospital.

Swansea.

A CASE OF CHYLIFORM ASCITES.

BY GEORGE A. CLARKSON, F.R.C.S. ENG.

IN connexion with the annotation on chyliform ascites published in THE LANCET of March 21st, p. 825, the notes of the following case, which came under my immediate observation while I was house physician to St. George's Hospital, may not be without interest.

The patient was a man, aged 52 years, who was admitted to St. George's Hospital on Dec. 7th, 1895, suffering from carcinoma of the liver. His previous history was unimportant and his health had only begun to fail nine weeks previously. On admission the pinched aspect of the man and the yellowish pallor of his skin were very noticeable but there was no jaundice. The *abdomen* was protuberant and was specially enlarged in the upper part, where over the region of the liver irregular rounded projections could even be seen. There was a considerable amount of fluid in the abdomen. The liver was greatly enlarged, reaching fully two inches below the umbilicus. It was hard and was raised into a number of nodulated projections. The abdominal walls were covered with enlarged veins, especially marked in the flanks. The urine contained lithates but no bile or albumin. Emaciation and loss of strength were rapid but the pain was ver very severe. By Dec. 26th the abdomen was so dis-nded with fluid and the breathing had become so embar-ssed that paracentesis was performed and ten pints of llow milk-like fluid were removed, but without any very eat relief, and the man died six days later.

The fluid removed was yellow in colour and of a milk-like aracter; it had a specific gravity of 1018 and gave an kaline reaction. On standing a pinkish gelatinous clot was rmed. Microscopically the fluid showed the presence of a rge amount of fat in the form of an emulsion and also merous cells containing fat in their interior. When shaken o with ether, fat was dissolved out and the ether left a reasy stain when dropped on paper.

At the necropsy, when the abdomen was opened, three nts of milky-looking fluid were found in the peritoneal vity. There was no peritonitis. The glands in the esentery were welded together with new growth and there as a large mass of growth behind the stomach almost ncircling the aorta. The liver, together with some masses f glands, weighed 13 pounds. It was full of firm growths he form of rounded lumps rising the size of erine oranges. On the surface they wer slightly ed from contraction. There was very little liver sub-e left uninvaded by growths. The left pleural cavity half full of chyliform fluid similar to that in the men. The right pleural cavity contained a similar nt of clear serum. With regard to the fluid in the men, no special leakage could be discovered, but the ptaculum chyli and thoracic duct must have been impli-d by growth which was very extensive in front of the and second lumbar vertebræ. No special cause could be d to account for the milk-like fluid in the left pleura. oscopically the growth was a spheroidal-celled carcinoma.

BATH ROYAL UNITED HOSPITAL.

ASE OF ACUTE ENTERIC INTUSSUSCEPTION CAUSED BY THE INVAGINATION OF MECKEL'S DIVERTICULUM; OPERATION; RECOVERY.

(Under the care of Mr. H. G. TERRY.)

FOR the notes of the case we are indebted to Mr. J. Beattie nlop, house surgeon.

A schoolboy, aged 12 years, was admitted into the Bath yal United Hospital on Dec. 16th, 1902, at about 9 P.M. he history of the case was that the boy had been quite well n that day until noon when he made a hearty dinner, but uring it was seized with some abdominal discomfort. He eturned to school at 1.30 P.M., but while there he had such ere attacks of pain in his abdomen that he was sent home. re his pain was thought to be due to indigestion and he s given peppermint water. As his condition did not im-ove Mr. E. L. Hunt, of Sherston, was sent for and he arrived out 4 P.M. He found the boy crying from pain and rolling om side to side. The patient's temperature was 96·5° F. d his pulse was 60. His pain was found to be most acute low and to the right of the umbilicus and there a sausage-aped tumour could be palpated three or four inches long d running up towards the liver. He had been vomiting rtially digested food and had passed a loose watery motion ntaining blood. Mr. Hunt diagnosed acute intussusception l sent him straightway to hospital—a drive of over 18 les.

On admission the boy's facies was not anxious. From e to time he had bouts of pain which were referred to region below and to the right of the umbilicus. His nperature was 99° and his pulse was 60 and small in lume. The abdominal wall was slack and moved with piration. There was very little distension. On palpation a sausage-shaped tumour was to be felt extending from the right iliac fossa to the right subcostal margin. It was firm, moveable, growing harder during the paroxysms of pain, and varying in size from time to time. Manipulation tended to make it smaller. Per rectum a tense swelling could be found in the right iliac fossa. Mr. Hunt's diagnosis was corroborated and operation was decided on at once.

The abdomen was accordingly opened to the right of the median line by Mr. Terry and an intussusception of the ileum forthwith presented itself. The tumour was 12 inches in length; it was tense, shining, cherry-red in colour, and the mesentery was twisted. Reduction was effected gradually and it was then seen that the intussusceptum was black in colour and that there was free fluid between the middle and internal layers. The blackness was dispelled gradually as reduction proceeded. At the end of the reduction, however, the apex of the intussusceptum gave way and was then found to consist of Meckel's diverticulum. The diverticulum was almost six inches in length and was swollen to the diameter of the small bowel, invaginated, and sloughing. Its invagination had evidently caused the intussusception of the ileum. This troublesome appendage was thereupon amputated at its junction with the bowel and the edges of the opening thus left were brought together by means of two layers of Lembert's sutures. The abdomen was then sewn up layer by layer. The boy bore the operation exceedingly well. On the next day he passed blood and flatus three times, and thenceforth made steady progress, his recovery, however, being somewhat delayed by the skin giving way, though the rest of the abdominal wall held well. He was discharged cured on Feb. 6th.

Remarks by MR. DUNLOP.—The above case is of interest from its bearing on the etiology of enteric intussusception. I must express my thanks to Mr. Terry for his kind permission to record this case, and to Mr. Hunt for the exceedingly good history which he sent us of it.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Acromegaly.—Bilharziosis.—Surgical Treatment of Gangrenous Bowel in Herniotomy.

A MEETING of this society was held on March 27th, Mr. HOWARD MARSH, the President, being in the chair.

Dr. H. A. LEDIARD (Carlisle) read a paper on a case of Acromegaly and Goitre. The patient was a woman, aged 43 years, who was born and had always lived in Cumberland. She had had amenorrhœa and headache dating from the last confinement, ten years previously. The features were characteristic, especially the lips, nose, lower jaw, and tongue, as were also the speech and expression of the face. The thorax was large, the ribs being massive and the hands being broadened. Sugar had been at one time present in the urine. For some years a bilateral goitre had been evident, but in June, 1902, the patient was sent to the Cumberland Infirmary for operation on account of dyspnœa with stridor and dysphagia due to pressure. The left side of the goitre was then removed and all these symptoms were relieved. The patient was exhibited to the society and her feeble muscular power was demonstrated. Radiographs of the hands and other parts were exhibited, together with the goitre which had been removed and microscopic slides. The usual features of acromegaly not present in this case were kyphosis, bi-temporal hemianopsia, sweating, and cyanosis. There was no trace of the general increase in size sometimes present, but the features of the face and the limbs were so greatly enlarged that the patient could not be recognised by her relatives and the muscular power was feeble.—Dr. W. PASTEUR asked whether the operation had in any way modified the character of the acromegalic condition.—Dr LEDIARD, in reply, stated that there had been no change in the pulse or temperature since the operation, but the patient had gained several pounds in weight.

Dr ANDREW DUNCAN read the notes of a case of Bilharziosis. The patient was a man, aged 30 years, lately in the 2nd Battalion East Kent Regiment. He had been fighting in the Orange River and Cape Colonies and was in Lord Roberts's march to Pretoria. In May, 1902, he began to itching at the end of the penis and a frequent desire to urinate, with great straining, but had at this time no hæmaturia He also had a lump in the left groin and great pain in the lower part of the back. The lump after rest went away. He returned to England in June, 1902, and on arrival first noticed a small clot of blood in his urine. Previously to the appearance of this he had severe pain and burning in the urethra. In July, there being a decided increase in the hæmaturia, he went into a country hospital and was there sounded for stone and examined by the Roentgen rays. During this time also growths appeared around the anus, for which mercury was prescribed on the supposition that they were specific. In January, 1903, the case was seen and at once recognised as one of bilharziosis by Mr. James Cantlie who sent him to the Branch Seamen's Hospital, where he was admitted under the care of Dr. Duncan. On admission the patient was anæmic and the urine contained blood, mucus, a small amount of albumin, and numerous ova of bilharzia. In the perineum there was a slight swelling over the raphé which disappeared after being fomented. There were three growths round the anus; one was conical and about half an inch in diameter and the other two were flattened with broad bases of half an inch. These on removal were seen to be papillomatous swellings stuffed with the ova of the bilharzia. The fæces passed by the patient were found to contain ova. There were no evidences of any growths in the rectum as far as the finger could reach. With regard to the ova passed by the rectum, according to Lancarol's teaching, the spines of these when occurring in the intestinal veins were always lateral, in contra-distinction to the terminal spines of the ova in the vesical veins. This, however, was not an invariable rule. Lieutenant P. S. Lelean, R.A.M.C., in his paper read last year before the Medical Society of London, stated that he had found rectal ova with terminal, and vesical ova with lateral, spines. In the treatment of this disease great difficulty had always been experienced; Dr. Guillemard went so far as to say that all treatment was useless. However, Lieutenant Lelean [illegible] drawn attention to the great benefit exercised by methy- [illegible] blue given in four-grain doses three times daily. He had [illegible] that ova died in less than 15 minutes when the stain [illegible] run under the cover glass. Dr. Duncan's patient had [illegible] treated according to Lieutenant Lelean's directions, but up to the present time there had been no appreciable difference in the amount of the hæmaturia; the deposit in the urine glass seemed less, but the colour of the urine was the same. For the first few days after his admission and before the methylene blue was administered the patient had been given tabloids of suprarenal extract but without any effect. Dr. Duncan now proposed to try liquid extract of male fern, as suggested by Mr. H. M. N. Milton of Cairo.—Dr. PATRICK MANSON remarked that condylomatous growths outside the anus were quite unusual, though internal growths were frequent in the rectum. The growths in the skin on the outside of the thighs in this case were also unusual; these also probably contained bilharzia. The lumps in the perineum were met with occasionally and their occurrence should be remembered by surgeons. The deposit of bilharzia at a distance from the normal habitat of the parasite was an interesting fact. Dr. Manson endorsed the statement that the bilharzia ova discharged from the bladder usually presented a terminal spine, though in certain cases the ova discharged from the rectum presented a lateral spine. He was inclined to believe that these two kinds represented two different species of the parasite. Treatment was most unsatisfactory and any new suggestion was an advantage.—Dr. W. P. HERRINGHAM, referring to the source of infection, asked why in bathing the worms should get into the portal vein.—Dr. PASTEUR asked what was the usual prognosis in this disease and referred to a case which had been sent to him as a case of renal calculus in which the patient eventually made a complete recovery without any special treatment.—Dr. H. BATTY SHAW remarked that the Boers in some districts of South Africa were well aware that the drinking of the water of certain streams was sure to produce bilharziosis.—Dr. DUNCAN, in reply, remarked that lateral spines had been found in bilharzia from the bladder. He believed that the disease was produced by drinking water which was contaminated. He had not yet seen a case in which treatment did any good.

Mr. G. H MAKINS read the notes of two cases illustrating the employment of Invagination and Stitching over Gangrenous Patches of Intestine in the Treatment of Strangulated Hernia. The first case was that of a man, aged 87 years, who for 16 years had been the subject of an irreducible right inguinal hernia. The patient was admitted to hospital 20 hours after the signs of strangulation had become marked. He was then in considerable pain, vomiting occurred at intervals, and the bowels were confined. The scrotum was red, tender, and considerably swollen. A herniotomy revealed a sac containing a quantity of red stinking fluid, six inches of small intestine with a small gangrenous patch perforated in the centre, and a single apple-pip free. The small gangrenous patch was inverted by the passage of four Lembert's sutures, the bowel was cleansed, the neck of the sac was removed, and the bowel was returned within the abdomen. No attempt was made to close the wound but this was plugged with gauze. The wound granulated up and the patient left the hospital cured after an uneventful course on the forty-eighth day. The second case was that of a male infant, aged nine weeks, an ill-nourished illegitimate child, the subject of congenital syphilis, in whom a small partial enterocele in a state of gangrene was found to exist. Two cases were also mentioned in which "doubtful" rings of gut had been stitched over and a third in which a gangrenous patch had been inverted successfully. The first case (that of the old man) was admitted to belong rather to the category of an intestinal perforation than to that of gangrene, but the second was an example of an ordinary gangrenous partial enterocele, and it was claimed that the method of treatment adopted could not safely have been replaced by any other. The opinion of Mr. W. Watson Cheyne and Mr. F. F. Burghard was quoted in favour of the adoption of the method of invagination in cases in which the condition of the gut was doubtful; reference was also made to some cases published by Professor C. J. Breitmann in which inversion of gangrenous patches was successfully carried out. The opinion of Professor Graser condemning the method as dangerous was also quoted, but Mr. Makins urged the value of the method in all cases where there was reason to believe the gangrene to be local and unaccompanied by diffuse infective inflammation of the bowel beyond. He also claimed that it was applicable to some cases in which resection could not be performed with safety to the patient as in the two instances which formed the subject of his communication.—Mr. L. A. DUNN referred to two cases of strangulated hernia which had been reduced *en masse*, in which similar pathological conditions had been successfully dealt with by this method. Another case, that of a boy, had been thus treated, but the boy died accidentally from suffocation. In a fourth case no harm had resulted by leaving the gangrenous spot of bowel.—Mr. A. A. BOWLBY remarked on the frequency with which some surgeons met with cases requiring resection of the bowel. His own experience was that such cases were few in number. There were, however, a certain proportion, especially cases of femoral hernia, which might be best dealt with by bringing together the peritoneum over the gangrenous or partially gangrenous bowel. For some years he had adopted this method rather than more extensive resection.—Mr. C. H. GOLDING-BIRD referred to the appearance of the gut in the first case mentioned by Mr. Makins, in which the resiliency of the bowel was lost. This appeared to him to be a most important point.—The PRESIDENT hoped that Mr. Makins's paper would do away with the too free resection of the intestine which was the practice of some surgeons. He had often adopted the practice advocated by Mr. Makins, especially in femoral hernia.—Mr. MAKINS replied.

OPHTHALMOLOGICAL SOCIETY.

Anophthalmos and Microphthalmos in a Chick.—The X-Rays in Trachoma.—Injuries to the Eye of the Child during Labour.—Dislocation of the Eyeball.—Exhibition of Cases and Specimens.

AN ordinary meeting of this society was held on March 13th, Mr. W. LANG, acting President, being in the chair.

Mr. E TREACHER COLLINS and Mr. J. HERBERT PARSONS communicated a paper describing the Microscopic Appearance of Sections through the Orbits of a Chick in which the right eye appeared to be congenitally absent and the left eye was abnormally small. In the right orbit a ring of hyaline cartilage, like that of the sclerotic, was found inclosing partly pigmented tissue, similar to that of the choroid There was no lens, retina, pigment epithelium, or optic nerve; there was thus a complete failure in development of all structures derived from neural epiblast. The essential element of an eye was a nervous mechanism which served to receive visual sensations for transmission to the brain. [illegible] ompletely absent the condition [illegible] as one of anophthalmos, not- [illegible] some of the subsidiary struc- [illegible] st. As far as Mr. Collins and Mr. Parsons had been able to ascertain, there was no case of congenital absence of the eye in which it had been satisfactorily shown by microscopical examination that the mesoblastic structures were entirely absent On the left side the chick had a microphthalmic eye in which the lens had failed to become separated from the cornea The capsule of the lens was adherent to the substantia propria of the cornea, [illegible] p. The adhesion [illegible] is ; above it had [illegible] surface of the lens ; below its growth had become arrested.

Mr. M. S. MAYOU (Cricklade) read a paper on the Treatment of Trachoma by the X Rays. The idea first occurred to him when treating rodent ulcer and lupus of the eyelid, on finding that no serious damage was done to the globe. The first case cured in this way was shown by him last June; since then several others had been successfully treated. The histological changes in living tissues exposed to the action of the x rays were then described, the most important change being a superficial irritation capable of being increased and accelerated by the simultaneous application of other irritants, such as copper sulphate. Most of the resulting leucocytosis was found around the trachoma nodules and the cells of rodent ulcer after x-ray treatment of these diseases, the reason for this being that they similarly acted as irritants. It was next pointed out that with care the amount of reaction produced could be regulated and that the varying degrees of reaction might be compared with the first three degrees of burns described by Dupuytren. Cases of prolonged exposure of the globe to the x rays were then instanced where the only bad effects produced, and those only temporarily, were falling out of the eyelashes and conjunctivitis ; this latter trouble was also found amongst workers in the x rays, and in them it could be prevented by the use of lead glass spectacles. Mr. Mayou found, with Fuchs and Kreidl (1896), that there was no bleaching of the visual purple by the x rays ; his experiments were carried out on rabbits and frogs. The results of treatment by the x rays were then compared with those produced by copper sulphate, jequirity, and other irritants and it was pointed out that there were less destruction of tissue and subsequent cicatrisation, as well as less pain, with the former method. The technique of the treatment was then described. The eyelids were everted (the operator's hands being protected by bismuth ointment and cotton gloves) ; the cornea was only exposed in severe cases where pannus was present. Owing to the infiltration set up difficulty was found in deciding when treatment should cease. Out of nine cases five remained well, one cleared up but recurred two months later, two others improved and were still under treatment, and in one case of corneal opacities following trachoma the vision had improved from perception of light to counting fingers at three feet. The advantages of this treatment were: (1) there was less resultant deformity of the lid ; (2) it was painless ; and (3) pannus cleared more thoroughly. The disadvantages were: (1) all patients did not react well to the x rays; and (2) it was sometimes difficult to tell when treatment should cease. Lantern slides of the histological changes produced by the x rays were shown and also two patients who had been cured by this treatment.—Remarks were made by the PRESIDENT, Mr. L. V. CARGILL, and Mr. S. STEPHENSON, the latter having seen the best results from the use of high-frequency currents which he had used somewhat extensively.

Dr. W. ERNEST THOMSON and Dr. LESLIE BUCHANAN (Glasgow) communicated some of the clinical and pathological observations which they had made upon Injuries to the Eye of the Child during Labour. After indicating the scope of the work done in this connexion Dr. Thomson gave a summary of the lesions in the 12 cases observed. These comprised expulsion of the eyeball, proptosis, injuries to the cornea, hæmorrhages into various parts of the eye, and retroversion of the lens and vitreous body without rupture of the globe. Dr. Buchanan described in detail three cases of lesion of the cornea—namely (1) rupture of the posterior elastic lamina with involvement of corneal tissue (healing); (2) rupture of the posterior elastic lamina and corneal tissue (unhealed); and (3) rupture of the posterior elastic lamina with abrasion. The points of similarity and difference were briefly explained. The identity of those cases of rupture of the posterior elastic lamina and corneal tissue with the cases already described as traumatic keratitis with linear opacity[1] from a clinical standpoint was pointed out and the etiology of other corneal opacities seen at birth was discussed. Remark was made upon the very unusual injury, retroversion of the lens and vitreous body, and the nature and origin of the case were somewhat fully explained. In conclusion, the subject of traumatic exophthalmos was dealt with and allusion was made to the connexion between it and the localised indentation of the cranial bones due to pressure against the sacral promontory. The subject was illustrated by macroscopic and microscopic specimens and diagrams.

Mr. J. B. LAWFORD read notes of a case of Complete Dislocation of the Eyeball forwards, occurring in a child, aged seven years, as the result of a fall against an iron fender. Reduction was easily effected under chloroform and recovery ensued with no defect of sight and no limitation of movements of the eyeball. Slight proptosis was noticeable for one month after the accident but no restriction of ocular movements could be detected even three days after the reduction of the dislocation.

The following card specimens were shown:—

Dr. BUCHANAN: (1) Separation of the Ciliary Body; and (2) Congenital Mal-development of the Cornea and Sclerotic.

Mr. MAYOU: Two drawings of the Normal Fundi, illuminated by the mercury vapour lamp.

Mr ARNOLD LAWSON: (1) A case of Paralysis of the Ocular Fibres of the Cervical Sympathetic with Aortic Disease; and (2) a case of Chronic Irido-cyclitis (probably Sympathetic) following a Rupture of the Globe 21 years previously.

Dr. THOMSON and Dr. BUCHANAN: Preparations illustrating the Effects of Injuries to the Eye of the Child during Labour.

Mr. W. H. JESSOP: Tumour in the Macular Region.

Mr W. W. SINCLAIR and Mr. J. H. PARSONS: Endothelioma of the Cornea.

Mr. R. W. DOYNE: (1) Melanotic Carcinoma of the Upper Lid with Pigmentation in the Lower Lid; and (2) Intraocular Hæmorrhage in a young man.

Mr. G. H. GOLDSMITH (Bedford): Hole in the Macula.

Mr. N. BISHOP HARMAN: Connective Tissue veiling the Optic Disc.

HUNTERIAN SOCIETY.

Exhibition of Cases.

A MEETING of this society was held on March 18th, Dr. STEPHEN H. APPLEFORD, the President, being in the chair.

Dr. F. J. SMITH showed a case of Multiple Lipomata. The patient was a man, aged 60 years, who first came under notice in September, 1901, for pain in the region of the heart which had been present on and off for a year. He had lost two stones in weight and complained that solid food produced great pain. The abdomen was rigid and the liver was slightly enlarged and tender. The case was diagnosed as one of probable malignant disease of the stomach, but the patient improved very rapidly under treatment by bismuth and opium. He was again seen in February, 1902, still complaining of some pain in the lower chest on the left side and there was then found to exist an obscure nodular swelling just below the ribs. Diagnosis was still obscure and the case was still watched with some interest. By May extensive subcutaneous growths had appeared above the clavicles and on the ribs and arms with signs of obstruction of the deep veins—enlargement of the subcutaneous veins of the chest—but he again improved very much under bismuth and opium and the arms diminished in circumference by four inches. About the same time he had an attack of profuse melæna, after which he was much better, and in July nothing was to be felt in the abdomen. He was not seen again till January or February, 1903. For the above notes on his history Dr. Smith was indebted to the kindness of his colleague, Dr. R. Hutchison. On the patient's admission to hospital the only other point of interest ascertained was that he suffered from free epistaxis in association with the strain of vomiting. On admission to hospital in March, 1903, his state was as follows. He was apparently a fairly well-nourished man; superficial examination showed that above the clavicles and on both upper arms there was a diffuse and profuse growth of what felt like subcutaneous fat; on both forearms there were lumps varying in size from that of a walnut to that of a golf ball, with an elastic semi-fluctuating feel, freely moveable on the muscles but incorporated with the corium; in fact, with all the physical signs usually associated with multiple and diffuse lipomata. The thighs presented a similar but much less marked condition than the upper arms. On the tendons of the wrist and on the tendon of the rectus femoris on each side there were one or two small lumps more firmly adherent to the tendon sheaths. On the left first rib at its junction with the sternum and over the right pectoralis major were one or two lumps of a much firmer consistency, feeling very suspiciously like glands infiltrated with some form of growth. The veins on the left side of the chest in front were rather more prominent than was usually the case though not sufficiently so to suggest serious blockage of large deep veins. Examination of organs gave no indications of disease, the air entered both lungs freely to the base without adventitious sounds or alteration of the natural ones; the heart beat was regular in rhythm and the sounds were satisfactory; and in the abdomen there was nothing to be felt that could be called abnormal unless it was a little tenderness to palpation in the upper abdomen generally. Dr. Smith gave the above details, or rather called the attention of the Fellows to the above points, and then considered the diagnosis. He stated that in his opinion there could be no doubt that the majority of the lumps were lipomata, but he was in doubt whether there were not also some glandular involvements; he hoped to be able to persuade the patient to allow one of the quasi-glandular lumps to be removed for microscopic examination. His suspicions were especially aroused by the history of gastric trouble, though he thought this might perhaps depend upon a chronic ulcer. He drew attention to the absence of any history of previous stoutness of the patient, a history which was commonly present in cases of multiple lipomata. He promised a further communication any new facts in the case.

---

[1] Transactions of the Ophthalmological Society, vol. xxii.

Dr. SMITH also showed a case of Leucocythæmia. The patient was a man, aged 32 years. His illness began in 1901 with a continued drowsy and sleepy feeling; he then noticed that his abdomen was swelling and that he got short of breath He was then told that his spleen was enlarged. He was admitted to hospital under the care of Dr. Smith in July, 1902, was treated with arsenic, and was discharged improved in September with a blood count showing—white corpuscles 171,600, red corpuscles 2 000,000, and hæmoglobin 45 per cent. He was readmitted to hospital on Feb. 21st, 1903, with loss of energy, shortness of breath, and swelling of the eyelids and ankles. He gave a history of hæmorrhage from the gums with attacks of faintness and giddiness; he had also cramps in the muscles. A blood count showed—white corpuscles 320,000 and hæmoglobin 50 per cent.; a stained film showed some poikilocytosis of the red cells and a few nucleated ones with every described variety of white cell with a preponderance of transitional forms; many blood platelets, in clumps and singly, were also present. The fundi oculorum showed no pathological changes of any kind. The spleen reached from the diaphragm to the pelvis. Dr. Smith remarked that the case showed no especial features of its own, but he had brought it as an example of a somewhat uncommon disease He was having a research carried out upon the uric acid in the urine by Dr. MacLeod in the Pathological Institute of the London Hospital.

Dr W. H. KELSON showed a man suffering from Ulceration of the Epiglottis, Inter-arytænoid Fold, and both Vocal Cords. Tubercle bacilli were present in the sputa. There were evidences of slight changes in the lungs. The patient complained chiefly of pain on swallowing, which had been markedly relieved by orthoform insufflations. He had also been getting hoarse for about a month. Dr Kelson, in replying to questions, said that orthoform powder had proved of great value in the relief of pain attending tuberculous ulceration.

Dr. T. GLOVER LYON showed a case of "Cured Phthisis." The patient was a girl, aged 11 years She was said to have had a cough with slight expectoration for two months, occasional slight spitting of blood, and had "wasted shocking." On admission to Victoria Park Hospital she was very thin, with shiny skin and pasty complexion, looking very ill. The physical signs were much the same as described later except that the heart's apex beat was normal in position. The patient rapidly improved in general condition and in eight weeks her weight increased from 4 stones 4 pounds to 5 stones 1 pound, an increase of 16 per cent. After two months in hospital the physical signs were as follows: the chest was well formed, moving slightly less on the left than on the right side; in front there was dulness and much increased resistance over the lung area above the heart, the apex beat of which was in the fourth interspace. There was tubular breathing with metallic (dry) crepitations. There were increased vocal resonance and decreased vocal fremitus. Behind there were slight dulness, metallic crepitations, and increased vocal resonance and vocal fremitus over the upper half. Cough and expectoration had entirely ceased and the child looked happy and well. The expectoration had ceased soon after admission and no examination of it had been made, but there was no doubt about the tuberculous nature of the disease The temperature had shown a tendency to rise from time to time up to 101° F., but the child had been allowed to get up without apparently any effect upon these rises of temperature.—Dr. SMITH, Mr. W. HARRIS BEST, Dr. W. H. KELSON, Mr. A. W. GALLOWAY, Dr. W. RAWES, and Mr. JOHN ADAMS discussed the cases.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A CLINICAL meeting of this society was held on March 20th, Mr. JOHN IRVING, the President, being in the chair.

Mr. J. G. E. COLBY showed a lad with Transposed Viscera

Dr. E. WARD exhibited two cases of (?) Molluscum Fibrosum

Dr. T. CHURTON showed: 1. A woman, aged 39 years, who had been under Anti-syphilitic treatment since December, 1901. At first the subclavian arteries, especially the left, were thickened and greatly dilated, the pulsation being visible above the inner and below the outer part of the clavicle. The carotids were similarly but less affected and pulsation was felt behind the manubrium. All these arteries now appeared to be perfectly normal. The other signs of syphilis had disappeared. Diffuse arteritis in an early stage was apparently as curable as diffuse syphilitic hepatitis in an early stage. 2. A woman, aged 49 years, with Aortic Aneurysm pulsating in the second left intercostal space. A systolic bruit was audible at the margin of the sternum, in the second interspace, and also over the trachea. 3. A case of Glycosuria of uncertain origin in a man, aged 56 years, in which "renal diabetes" had been excluded by *finding* an excess of sugar in the blood by Williamson's test.

Mr. W. H. BROWN showed some Results of Plastic Surgery.

Dr. J GORDON SHARP showed: 1 A man, aged 40 years, exhibiting Infiltration of the Soft and Hard Palate, Epiglottis, Inter-arytenoid Region, and Ventricular Bands, probably tuberculous in nature, although no bacilli were found in the sputum. The condition had greatly improved under the local application of 75 per cent. lactic acid. The same patient also showed great hypertrophy of the lingual tonsil causing no inconvenience and untreated. Six months previously he had pleurisy. 2. Three cases of Vaso-motor and Trophic Disease treated for some weeks with dried adrenal gland and cod-liver oil. During the past month five grains had been given twice a day. Case 1 (that of a girl, aged 13 years) was one of true Raynaud's disease, showing remnants of necrosis of the soft parts of the fingers and toes. Last winter the girl had to be confined to bed on account of the sores. Under the present treatment she had this winter been able to move about and to do household work; all saving one sore on the toe had healed. Case 2 (that of a girl, aged 11 years) was considered to be one of severe "broken" chilblain with large areas showing local asphyxia The sores had nearly all healed and the nutrition of the skin and parts in general had improved. Case 3 (that of a girl, aged nine years) was one of doubtful Raynaud's disease showing the results of malnutrition of the nails of the *fingers and toes, sores of the soft parts, areas of asphyxia,* and glossy skin. Although on first consideration a substance like adrenal gland which contracted vessels would appear to be contra-indicated in local syncope, yet, as suggested by Dr A Mantle, the agent might act beneficially by raising the blood pressure

Mr H **LITTLEWOOD** showed ten cases of Acute Perforated Gastric Ulcer which he had successfully operated on during the last seven years. In all the cases the perforation was in the anterior wall of the stomach and nearer the lesser than the greater curvature. The quantity of extravasated material varied from a general flooding of the peritoneal cavity to a small amount in the region of the ulcer and hypochondriac regions. Case 1 —The patient was a young woman, aged 18 years. Operation was performed on May 2nd, 1896, seven hours after perforation. Much extravasation was present The ulcer was excised and the stomach opening was closed with interrupted silk sutures. The abdomen was drained Case 2.—The patient was a young woman, aged 18 years Operation was performed on July 21st, 1896 six hours after perforation The ulcer was excised and the opening in the stomach was closed with interrupted silk sutures Much extravasation was present The abdomen was drained. Case 3 —The patient was a single woman, aged 28 years. Operation was performed on April 11th, 1899, five hours after perforation. The ulcer was excised and the stomach was closed with interrupted silk sutures. There was not much extravasation The abdomen was closed without drainage. Case 4.—The patient was a single woman, aged 28 years Operation was performed on Dec. 11th, 1900, five hours after perforation The ulcer was excised and the stomach was closed with interrupted catgut sutures. The abdomen was closed without drainage Case 5 —The patient was a single woman, aged 24 years Operation was performed on Sept. 11th, 1902, about 24 hours after perforation The ulcer was excised and the stomach was closed with a continuous catgut suture Extravasation was limited to the upper part of the abdomen The abdomen was closed without drainage. Case 6 —The patient was a single woman, aged 24 years, Operation was performed on Oct. 25th, 1902, about 18 hours after perforation. The ulcer was excised and the stomach was closed with a continuous catgut suture A good deal of extravasation was present. The abdomen was drained Case 7.—The patient was a single woman, aged 20 years Operation was performed on May 15th, 1902, about 14 hours after perforation. The ulcer was excised and the stomach was closed with a continuous catgut suture There was much extravasation The abdomen was drained. Case 8.—The patient was a single woman, aged 23 years. Operation was performed on Feb. 26th, 1903, about ten hours after perforation. The ulcer was excised and the stomach was closed with a continuous catgut suture There was not much extravasation. The abdomen was closed without drainage Case 9 —The patient was a young woman, aged 19 years Operation was performed on March 1st, 1903, eight hours after perforation The ulcer was excised and the stomach was closed with a continuous catgut suture Not much extravasation was present The abdomen was closed without drainage Case 10 —The patient was a young woman aged 18 years Operation was performed on March 16th, 1903 The ulcer had perforated on March 12th There was very little extravasation, as the stomach around the perforation was adherent to the under surface of the liver The ulcer was excised and the stomach was closed with a continuous catgut suture The abdomen was closed without drainage

Dr. T. **WARDROP GRIFFITH** showed (1) Cases of Raynaud's Disease; (2) a case of Cerebral Diplegia; and (3) an extensive Rodent Ulcer which had undergone complete cicatrisation under the use of the x rays during five months

Mr. A L. **WHITEHEAD** showed: (1) A case of Traumatic Ocular Paralysis; (2) a case of partial Embolism of the Central Artery of the Retina; and (3) a case of Detachment of the Retina

Dr. **DOUGLAS SEATON** showed: (1) Two cases of Congenital Syphilis; and (2) a case of Malignant Disease of the Floor of the Mouth

Mr. H R. **BEALE** showed a case of Lesion in the Middle of the Pons There was palsy of the left internal rectus for conjugate deviation to the right, but not for convergence; the pupils were normal. The superior obliques were normal Sensation in the face was normal Paralysis of the muscles of mastication, palsy of both external recti (greater on the right), and facial palsy were present, and deafness existed on the right side. The remaining cranial nerves were normal Palsy, incoördination, and numbness of the right arm and hand were present There was increase of reflexes on the right side The patient suffered from headaches and vomiting.

Mr. R **LAWFORD KNAGGS** showed a patient in whom the Great Sciatic Nerve had been severed six years ago by a Crowbar that had transfixed the thigh The nerve had been sutured on the following day. The patient could walk without a noticeable limp but sensation over the lower part of the leg and foot was still very imperfect Considerable improvement had taken place during the last two years and was continuing

Dr. E F. **TREVELYAN** showed: 1. A series of cases of Laryngeal Affections in Phthisis among which were (*a*) a lad with a fixed left cord, enlarged glands in the neck, tubercle bacilli in the sputum, and no definite abnormal signs in the chest, (*b*) a man with persistent hoarseness and no obvious change in the larynx; and (*c*) a man with laryngeal obstruction due to infiltration of the ventricular bands. 2 A case of Tabes Dorsalis of long standing in a man who had worn a shade for many years on account of diplopia. Removal of the shade caused a great increase in the ataxia altho [illegible] Mark [illegible] taken [illegible] by a [illegible]

Dr S M. **HEBBLETHWAITE** showed a case of Trichocephaliasis

LIVERPOOL MEDICAL INSTITUTION.

Pathology of Progressive Muscular Atrophy.—Acute Intussusception with Ulceration of the Intestine —Exhibition of Specimens

A MEETING of the Pathological and Microscopical Section of this society was held on March 26th, Dr. R J. M. **BUCHANAN** being in the chair.

Dr A. W **CAMPBELL** gave an account of the histology of two cases of Progressive Muscular Atrophy and made special [illegible] to changes in the Cortex Cerebri In both instances [illegible] s, the spinal cord, and the [illegible]: in both also a serial exa[illegible] in the whole of its extent revealed the remarkable fact that in the part of the ascending frontal gyrus and paracentral lobule which an examination of healthy brains proved to be the normal residence of the giant cells of Betz scarcely any of these elements were to be discovered, and their disappearance was associated with a general distortion of the cells which remained, atrophy of efferent fibres, and distension of cortical blood-vessels The ascending parietal and other neighbouring convolutions were relatively healthy. The view that the spinal changes in progressive muscular atrophy were primary was rendered unstable by the findings in these two cases, because from an experience of the cortical alterations in instances of interference with the system of motor neurons at a lower level (cases of myelitis and amputation) it was idle to suppose that a complete retrograde destruction of the cells of Betz could occur during the progress of a disease which usually did not last more than three years The alternative views mentioned were that either the cortical changes were primary or else in progressive muscular atrophy an expression could be seen of a general and more or less simultaneous affection of the whole system of motor neurons The fact that the alterations were entirely confined to the area of distribution of the cells of Betz gave support to the view previously expressed by Dr. Campbell on histological grounds that in man the topography of the motor area was analogous to that which Professor C S Sherrington and Dr A. S. F Grunbaum had defined in the anthropoid ape; further since sensation was unimpaired in cases of progressive muscular atrophy, the changes noted could be used as an argument against the theory of the mixed sensori-motor function of the central convolutions The paper was illustrated by drawings and microscopic sections and in one of the latter an abundance of muscle spindles was seen remaining in an extremely atrophied muscle, an appearance which strengthened the view that these bodies were concerned with muscle sense.—Dr. W. B **WARRINGTON** considered that Dr Campbell had made an important addition to the pathology of this disease since the complete disappearance of the Betz cells had not previously been described. It was recognised that the anatomical changes in the great cortico-spinal efferent tract were found most extensively marked in its peripheral distribution and were not often seen in the higher cerebral regions This, however, did not imply a peripheral origin but indicated that the anatomical change first appeared in the position most remote from the trophic centre. Etiologically no toxic influence had been traced and the view appeared probably correct that the disease was primarily due to some inherited lack of durability and unusual stress on the motor neuron. Such considerations also led to the acceptance of the view that the disease first began in the great pyramidal cells. Dr. Campbell's demonstration of the integrity of the muscle spindles was also important —Dr GRUNBAUM and Dr. J. WIGLESWORTH also spoke and Dr. CAMPBELL replied.

Dr. LLEWELLYN A. MORGAN read a note on a case of Acute Intussusception in an Infant associated with Ulceration of the Intestine.—Mr. R. W. MURRAY said that the case was exceptionally interesting on account of the remarkable combination of the lesions. It was the only case of intussusception he had met with in which the invagination originated above the ileo-cæcal valve and it was the only case he had seen in which tuberculous ulceration of the gut had been the cause of the intussusception.

The following specimens were shown :—

Dr R. T. BAILEY : (1) Acute Plastic Pericarditis ; and (2) the Lower Jaw of a Child who had been the subject of congenital syphilis.

Mr. F. C. LARKIN : (1) Sections of a Carcinoma Mammæ densely Infiltrated with small Polynucleated Round Cells ; and (2) Adenomatous Tumour which filled the lower half of the antrum and invaded the nose, the palate, and the alveolus. Its structure was that of a simple mucous gland.

Dr. WARRINGTON : Specimen and Sections from a case of Collapse of the Lung, Bronchiectasis, and Gangrene after Pneumonia.

Dr. E. T. DAVIES : Fibroid Tumours of the Uterus

Mr. G. G. HAMILTON : Microscopical sections from a Sarcoma originating in the Tendon Sheath of the Tibialis Posticus.

Dr. J. HAY : Specimens from a case of Actinomycosis. The patient was a girl, aged 15 years, the first noticed lesion was a submammary abscess. The disease at present affected the left lung and there were secondary foci in the brain, scalp, and skin of the extremities and trunk.

Mr. W. THELWALL THOMAS : (1) Carcinoma of the Kidney removed from a woman, aged 58 years ; it occupied the lower half of the organ ; the cells of the new growth were large and showed some melanosis (Mr. Thomas considered it adrenal in origin) ; (2) a Necrotic Clavicle following Osteomyelitis removed from a man, aged 24 years ; and (3) Tuberculous Disease of the Mammary Gland in which the axillary glands were enlarged but not tuberculous.

The following members took part in the discussion of the specimens : Dr. BUCHANAN. Mr. F. T. PAUL, Mr. K. W. MONSARRAT, and Dr. F. H. BARENDT.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Operative Treatment of Enlarged Prostate.—The Surgery of the Prostate.

A MEETING of this section was held on March 6th, Mr. L. H. ORMSBY, the President, being in the chair.

Sir WILLIAM THOMSON read a paper on the Operative Treatment of Enlarged Prostate. He read the notes of five cases on which he had operated, following the method described by Mr. P. J. Freyer. The patients' ages ranged from 53 to 75 years. One died from ether bronchitis and the others completely recovered. The results attained had been surprising and none of the patients, who had all suffered from retention and cystitis many times and had been using a catheter for varying long periods, had required any instrumentation since. In one case he had removed the prostate in a single mass, including the urethra. In the same case it had been necessary to plug the bladder some hours after the operation owing to hæmorrhage. He described a thin rubber oval disc which he had devised for such cases instead of the gauze plug, the removal of which was painful and disturbing. The disc had a long ligature carried through it and this was next tied to a catheter and brought out through the urethra. Traction made pressure on the site of the bleeding. A ligature carried through the rubber near the edge served for extraction when the bleeding had stopped. This rubber did not adhere, and as it was thin and was extracted edgewise there was no disturbance of parts and no anæsthetic was required.

Sir THOMAS MYLES read a paper on the Surgery of the Prostate, in which he advocated the perineal method of reaching the prostate.—Mr. A. B. MITCHELL said that the subject was one of great interest. He congratulated Sir W. Thomson on the success of his operation. The great questions for the general practitioner were : (1) When should operation be recommended? and (2) what was the prospect of relief? Undue frequency of micturition was due to cystitis and was the most imperative of all indications Rapidity of procedure was a most important element in all operations on old men. Every moment an aged patient was kept on an operating table was fraught with danger, and great danger. His own experience was in favour of the suprapubic route, but he was very favourably impressed with the operation described by Sir Thomas Myles and would like to have some statistics of cases actually operated on according to his method.—Mr. JOHN LENTAIGNE was in favour of the suprapubic method ; he had no experience yet of the perineal, but the suprapubic was so easy that he had been tempted to employ it in each of the few cases he had had an opportunity of operating on. He did not accept the statement that pneumonia after operation was always septic. He had often seen pneumonia of a severe type in other operations where the wound healed aseptically and in the most perfect manner.—Sir T. MYLES and Sir W. THOMSON replied.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 19th, the President, Dr. J. Robertson, being in the chair.—Dr. Arthur J. Hall showed a specimen of Cerebellar Tumour and gave an account of the case.—Professor C. J. Patten showed a series of models in wax and plaster illustrating the Topographical Anatomy of the Abdominal Viscera. The originals from which the models were made were first thoroughly hardened by formalin injected through the femoral artery. Most of the specimens were from adult male subjects in which no sign of visceral disease was apparent. The models exhibited were : (1) the kidneys and their relations to the vertebral column, lower ribs, and pleura ; (2) front view of the abdominal viscera seen on removal of the anterior abdominal wall ; (3) a wax model of all the abdominal organs on the reconstruction method ; (4) the pancreas, duodenum, and spleen, with the relations of the branches of the abdominal aorta and inferior vena cava ; (5) wax models of fœtal lungs (human), of lungs of the *Cynocephalus babuin* and of the *Hylobates hainanus ;* (6) a model in plaster of the entire trunk of *Hylobates hainanus*, showing the relations of the thoracic and abdominal organs, especially to the vertebral column ; and (7) another model of the same animal showing the form of the pancreas, duodenum, and spleen.—Dr. J. Robertson read a paper on an Outbreak of Typhoid Fever due to the Consumption of Oysters in Sheffield. Every year there had been from 20 to 30 more or less isolated cases of typhoid fever which possibly might have been due to the consumption of polluted oysters. On one or two occasions groups of as many as two or three cases appeared to have occurred from one oyster shop. As a general rule it was exceedingly difficult to be quite certain that the infection was derived from particular oysters. This arose firstly from the difficulty of tracing the source of the oysters, secondly from the fact that everybody who consumed oysters did not contract the disease, and thirdly from the fact that in towns where typhoid fever was endemic it was very difficult to trace the source of infection. The occurrence, however, of these isolated cases every year, many of which derived their oysters from one particular district, gave rise to suspicion that the oysters from at least one source spread typhoid fever. During last summer between August 14th and Sept. 18th 43 cases of typhoid fever were notified in Sheffield. This was a much smaller number than was usual at that time of the year. On examining these cases it was found that in no less than 20 of them patients had partaken of oysters from Cleethorpes within the previous 25 days. Oysters came directly from Cleethorpes layings to Sheffield, and in Dr. Robertson's opinion this was an important point. Oysters which were stored in clean water or even in shops lost their power of conveying the disease. In Sheffield there was every chance that the oysters from Cleethorpes were fresh. Most of the patients suffering were persons of the working class who had either been to Cleethorpes for a holiday or had bought Cleethorpes oysters in Sheffield or had had them sent from Cleethorpes. The period which elapsed between the consumption of oysters and the notification of the disease as typhoid fever varied up to 25 days—in the majority of cases the period varied between 10 and 15 days. Two of the cases were certified to be typhoid fever within seven days of the last occasion on which oysters were partaken of. In the well-marked outbreak at the Wesleyan University, Connecticut, the period varied from 13 to 33 days. After describing the oyster layings at Cleethorpes and quoting from the report of the Local Government Board Dr. Robertson described some of the other oyster layings and alluded to the difficulties which the oyster growers had in obtaining sites suitable for rearing oysters which were quite free from sewage pollution. He recommended that the profession should give warning against oysters until some guarantee was obtained of their freedom from all risk.

British Balneological and Climatological Society.—A meeting of this society was held on March 18th, Dr. E. Symes-Thompson, the President, being in the chair.—Dr. F. A. Mouillot (Harrogate), in introducing a discussion on Dietetic Factors in Health Resort Treatment, said (1) that a considerable portion of diseases treated at spas was due to faulty metabolism and that gout, obesity, and glycosuria were the chief of these diseases and were closely connected; (2) that gout in its widest sense was due to the development of certain poisons in the process of digestion and that these poisons were best limited by a simple meat dietary; (3) that it was irrational to consider food or drugs solely from the point of view of their acidity or supposed solvent power on uric acid; (4) that if the patient was properly dieted at home no marked change ought to be made in the diet at the spa, more particularly should the quantity of food not be restricted whilst undergoing a treatment which made a great strain on the activity of the system; (5) that the education which the patient received as to the regular consumption of non-alcoholic fluid apart from meals was a useful one; (6) that an attempt to treat obesity by withholding fluids was to be condemned as leading to the production of serious disease and ill-health and that though it was right to diminish the quantity of fluid taken at meals it was wrong not to make up for that limitation by giving water apart from meals; and (7) that alcohol should be taken in very limited quantities, if at all, and that in the case of gout whisky, still Moselle and still cider seemed least harmful.—Dr. Harry Campbell pointed out that for the long period which elapsed bef [illegible] learnt to cook his food and to till [illegible] ch were limited and subjected to [illegible] and insalivation that very small [illegible] passed into the stomach; whereas in this stage of abundant starch and imperfect mastication the stomach and intestines were flooded with undigested starch which gave rise to many evils.—Dr. Preston King (Bath) pointed out that while the Continental system of a more strict diet was suited for certain cases there were more for which it was not adapted, and he would be sorry to see it introduced here. Each case must, in dietary as in other things, be treated on its merits.—Dr. Léon Blanc (Aix-les-Bains), speaking specially of the diet in gouty cases, said that the diet regulations were not very strict in France because the ordinary food was comparatively light. He gave mixed diet, including meat, only twice a day, and preferably beef and mutton, which must be boiled if possible. Game, venison, pork, and preserved meat were forbidden. All vegetables were good, and fresh fruits, especially acid fruits, were taken between meals. Alcohol must be proscribed. Pure water (Massonat water) should be given with a little white wine or lemon-juice, &c. All alkaline preparations must be prohibited.—Dr. Schott (Nauheim) said that every case must be provided for according to its own individual peculiarity. He advocated a mixed diet in heart cases, and small and frequent meals, generally at intervals of three hours, and of high nutritive value. Alcohol should be taken in a state of high dilution. It was unquestionably the case that certain wines well borne by continental patients produced acidity in some of the English, and in such cases it was better to fall back on small and regulated quantities of whisky or brandy in a state of free dilution.—Mr. A. G. S. Mahomed (Bournemouth) and Dr. George Lorimer (Buxton) also made some remarks, after which the discussion was adjourned.

Harveian Society of London.—A meeting of this society was held on March 19th, Dr. W. Winslow Hall, the President, being in the chair.—Mr. F. Jaffrey showed (for Mr. Crisp English) a girl, aged four years, whose gait had become waddling when she was two years of age and had remained so, but without giving any pain. There were some atrophy of the muscles about the hip and an inch shortening of the limb. The case was thought at first to be one of coxa vara, but a skiagram showed it to be a well-marked instance of congenital dislocation of the hip. Mr. Jaffrey asked for suggestions as to treatment.—Mr. Noble Smith considered the case a very favourable one for treatment by Lorenz's method.—Dr. Sidney P. Phillips showed an extreme case of Osteo-arthritis of the left knee in a man, aged 48 years. The patient had rheumatic fever at the age of 15 years and at the age of 33 years he began to suffer from osteo-arthritis. Many joints were now affected, but the left knee was enormously enlarged and was tense and elastic. A small amount of fluid withdrawn by aspiration proved to be sterile.—Mr. Jaffrey thought the treatment by massage and hot-air baths daily should be followed. Probably at least two or three different complaints were included under osteo arthritis. Very likely some cases were of bacterial origin. He had found guaiacum and sulphur of use in many instances.—Mr. Noble Smith said that no doubt the pathology of the disease differed in different cases, but in all cases there was increased tension in the bone. In chronic bone inflammation, therefore, he was in the habit of adopting "bone drilling." In tuberculous disease drilling was remarkably effective. It also relieved pain in the early stages of rheumatoid arthritis. He showed the drill which he generally used.—Dr. G. A. Sutherland remarked on the failure of drugs either to relieve the symptoms or to cure the disease. Whatever the nature of the original poison he thought it acted ultimately on the central or peripheral nervous system, so that the pains and deformities of the later stages were really dependent on a nerve lesion.—Dr. E. Cautley said that one definite type of osteo-arthritis was symmetrical in form and often occurred in acute attacks, simulating subacute rheumatism, and usually it began in the metacarpo-phalangeal joints of the first and second fingers. This type was most common in young women between 15 and 25 years of age; sometimes it occurred in young children and was frequently seen in later life in a more chronic and less severe form. It was incurable. Another type of the disease [illegible] in origin. A third form affected the larg [illegible] followed an inju [illegible] of nerve origin, [illegible] to some toxin. Some cases were preceded by neuralgic pains for months before any joint lesion was noticed.—The President advocated the use of cod-liver oil—at all events, in certain [illegible] Dr. W. J. Harris showed a woman [illegible] —Mr. [illegible] ering [illegible] Daniel [illegible] with [illegible] t the [illegible] also showed two cases of Monarticular Osteo-arthritis of the Elbow-joint.

Manchester Medi [illegible] a recent meeting of this [illegible] being in the chair, a disc [illegible] tration of the Vaccination Act.—Mr. David Owen in opening the discussion contended that all vaccination performed by a registered medical practitioner should be paid for by the State at the same rate as public vaccination, provided that the standard of the Local Government Board was reached. In this way the quality of vaccination in the country would be greatly improved, especially if it were made subject to some form of inspection which as "surprise visits" might be carried out without any great additional expense, and in estimating this expense the enormous cost of small-pox to the community should not be forgotten. It was important to reconcile public opinion to compulsory vaccination and revaccination, and given a free choice of medical man much of the present opposition would be removed. From statistics which he had collected he had no doubt that in Manchester at least the greater number of vaccinations did not reach the standard laid down by the Local Government Board, which might be taken as the standard of efficiency. There was nothing in the nature of the present Act to reduce the divergence between the vaccination results of the public vaccinators and those of private practitioners. The unsatisfactory nature of the present Act had been the subject of comment by members of the profession in the columns of the medical journals for nearly two years.—Dr. John Scott argued that the one essential of improvement was the proposition advanced by Dr. F. T. Bond of Gloucester and others that vaccination should be made a department of public health and placed under the control of the sanitary authorities. It was to be hoped that in the next Bill revaccination at the age of 12 years, as recommended by Mr. Jonathan Hutchinson and Sir W. Guyer Hunter before the Royal Commission, would be made compulsory. Dr. Scott offered three suggestions: (1) that vaccination should be placed in the public health department of the county council authority; (2) that the public vaccinator should do nothing else but this work; and (3) that the coöperation of medical men in educating the public in the efficiency of vaccination should be enlisted.—Dr. E. Vipont Brown said that the reason why such an enormous proportion of children were not vaccinated efficiently was that it sometimes paid the general practitioner to vaccinate inefficiently. When parents took their children to a private practitioner in preference to the public vaccinator it was very often in the hope that the former would put on only one mark, or at most two marks. Indeed, that was what they were constantly asked to do. The remedy was obvious: to make all general practitioners public vaccinators and to let the State pay them for efficient vaccination—and for efficient vaccination only. Then self-interest would cause them to educate their patients to understand the advantage of efficient vaccination as defined by Government and they would persuade them to submit to it.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 18th, Mr. J. Mackie, the President, being in the chair.—Mr. A. R. Anderson read notes of Three Cases of Operation for Perforated Gastric Ulcers. Two of the patients were shown and the third was stated to be well. When the position of the ulcer was such that the proceeding was feasible Mr. Anderson recommended that the whole ulcer should be excised and that the stomach should be sewn up by a double continuous suture. This, in his opinion, gave better results in that on recovery from the operation all symptoms of indigestion entirely disappeared, whereas when the ulcer was simply turned into the stomach and the perforation thus closed symptoms of indigestion frequently persisted.—Mr. W. M. Willis said that his experience bore out this contention and that excision was preferable to merely turning in when possible.—Dr. W. B. Ransom delivered an address on Public Measures for the Prevention of Tuberculosis. The lines which the education of the public in the matter of hygiene as a means of prevention of tuberculosis should follow were indicated. The question of the housing of the poor in relation to tuberculosis was alluded to; and the advisability of certain measures being adopted by the municipality as a means of checking the spread of the disease was suggested. It was resolved, on the motion of Dr. P. Boobbyer (medical officer of health of Nottingham), seconded by Dr. C. H. Cattle, that the meeting should be adjourned in order that this important question might be adequately discussed.—Dr. Ransom then gave notice that at the adjourned meeting he would move—

> That in the opinion of this society voluntary notification of phthisis is desirable.

——The adjourned meeting was held on Feb. 25th, the President again being in the chair.—Dr. Ransom having briefly introduced the subject of his address it was discussed by Dr. Boobbyer, Dr. F. H. Jacob, Mr. Wood, Dr. Mackenzie, Dr. W. E. Tresidder, Dr. W. Hunter, Mr. J. J. Dabell, and Dr. J. F. Blurton.—Dr. Ransom replied and then brought forward his motion as given above. He defined "voluntary notification" as referring both to patient and medical man. The object of such notification was, he suggested, that steps might be taken by the municipality, either by means of lady sanitary inspectors or of assistant medical officers of health, to carry out certain hygienic measures advisable in this disease and for the purpose of educating the public in the means for the prevention of infection.—The motion was seconded by Dr. Boobbyer and a spirited discussion ensued in which Mr. Wood, Mr. Anderson, Dr. E. C. Kingdon, Dr. Blurton, Mr. T. Geraty, Mr. Dabell, Mr. J. Thompson, Dr. Mackenzie, Dr. Hunter, and Miss Sarah Gray, F.R.C.S. Irel., took part.—On the motion being put to the meeting 11 members voted in its favour and six against it, whilst seven members remained neutral.

MIDLAND MEDICAL SOCIETY.—The ninth ordinary meeting of this society was held on March 18th, Mr. H. Langley Browne, the President, being in the chair.—Mr. A. Lucas showed a girl, aged 16 years, in whom he had Excised the Superior Maxilla nine months previously. The cavity had closed with the exception of a small aperture a quarter of an inch in diameter. With the aid of an obturator kept in place by a spring from the lower jaw practically the whole of the resulting deformity was obliterated and the patient was able to speak and to masticate normally. The growth for which the operation was performed was an osteoma arising in the antrum of Highmore. It had been present for many years and lately had increased rapidly. It was causing much disfigurement of the face and was encroaching on the orbital and nasal fossæ.—Mr. C. A. Leedham-Green showed a case of Xeroderma Pigmentosum in a child, aged seven years.—Dr. O. J. Kauffmann showed a case of Sarcoma, primary in the arches or spinous processes of the lumbar vertebræ. There were deposits in the spinal dura mater beneath the primary growth, but to the naked eye the cord itself appeared to be free from damage of any sort. There were secondary deposits in the retro-peritoneal lumbar glands and many in the liver. The patient was admitted to hospital with pronounced spastic paraplegia and symptoms locating the lesion in the upper lumbar segment. The history was that he had gone to work in perfect health one day in July, 1902, and that while working he had the sensation of having caught cold in his back. He walked home with difficulty and went to bed, and next morning he was unable to rise. He never again put his foot to the ground. He was admitted to hospital in December, 1902, and was then entirely paralysed in the legs, and soon he developed overflow-dribbling from the bladder and cystitis. A month later, without any change of symptoms, excepting the development of a slight boss in the lumbar region, he died. It was thought that the rapid onset of paralytic symptoms had been due to thrombosis of a nutrient artery produced by the presence of the tumour.—Dr. J. Douglas Stanley showed a specimen of Dilated Heart from a patient who also suffered from Pyloric Stenosis. The patient, a male, aged 38 years, had suffered from pain in the epigastrium after food for a year. There was occasional vomiting. The appetite was voracious. Death was due to collapse. On post-mortem examination the pyloric stenosis appeared to be caused by fibrosis round a simple ulcer situated in the pylorus.—Mr. A. W. Nuthall showed a specimen of Diffuse Carcinomatosis of the Intestine.—Mr. Christopher Martin read (for Mr. Edge) a note on the After-progress of a Case of Oöphorectomy for Recurrent Cancer of the Breast.—Dr. A. D. Heath read a paper on Scarlatiniform and Erythematous Eruptions.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—A meeting of this society was held on March 13th, Dr. V. H. Wyatt Wingrave, the President, being in the chair.—Dr. J. Dundas Grant showed a case of Deafness due to Myxœdema in a female, aged 59 years. The deafness in this case was a combination of nerve deafness and obstructive deafness and while the general symptoms had improved under thyroid treatment the deafness had remained much the same.—Dr. Atwood Thorne inquired what evidence there was to the effect that the deafness in this patient was due to myxœdema.—Dr. Dundas Grant, in reply, said that myxœdema was admitted to be a cause of deafness and that he had seen such cases enormously improved as regards their hearing when thyroid treatment was used.—The President also said that he considered myxœdema to be a cause of deafness.—Dr. W. Jobson Horne said that he had seen a small series of cases of myxœdema complicated with deafness and his experience was that the deafness did not improve with thyroid treatment.—The President read, on behalf of Mr. Mayo Collier, who was unable to be present, the notes of a case of Suppuration of the Frontal Sinus.—Mr. J. E. McDougall read a short paper on a New Method of dealing with Adherent Soft Palate.—Dr. L. H. Pegler read a short paper on an Unusual Experience after Partial Turbinotomy. The essential feature of the case was that there was a delay in healing but a successful result was at last brought about by the accidental application of a solution of iodine ("Mandl's pigment") stronger than was intended.—The President showed (1) a case of Tuberculous Granuloma of the Larynx in a female, aged 26 years; (2) a case of Lupus of the Larynx occurring in a boy and almost entirely confined to the epiglottis; and (3) a case of Aphonia due to disease of the larynx the nature of which was uncertain.—The President also showed a case of Bilateral Adductor Paralysis following tonsillotomy in a girl, aged 14 years. She remained aphonic for 14 days after the operation, and at once regained her voice after a single application of the interrupted current. He felt inclined to regard the nitrous oxide gas, which was the anæsthetic used, as the cause of the paralysis.

CLINICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on March 17th, Dr. T. Arthur Helme being in the chair.—Mr. F. H. Westmacott made a communication on Nasal Obstruction and its Causes. He indicated the leading symptoms of this condition—namely, inability to breathe freely through the nose, a certain facial expression, "adenoid facies," present in nearly all cases, discharge from one or both nostrils forward or into the nasopharynx, thickness of speech or voice, the so-called nasal voice, broadening of the bridge of the nose, a short upper lip, and open mouth. Of the various nervous or reflex symptoms he mentioned headache, cough, asthma, deafness, convulsions (epileptiform in character), as well as a dull mental condition and inability to concentrate the mind and attention on any subject (sometimes called aprosexia). Loss [illegible] be present in some cases. [illegible] e "pigeon-breasted," the [illegible] negative pressure in the [illegible] r cartilages. In a child the occurrence of a unilateral obstruction with a discharge more or less offensive and blood-stained pointed strongly to the presence of a foreign body, whilst in an adult a similar condition might indicate an empyema of the accessory cavities. Should the patient be able to detect an offensive odour in the discharge, then in all probability the antrum of Highmore was affected, but if no odour was detected by the patient, or if there was loss of smell on that side, suppuration in one or more of the upper accessory cavities was indicated.—Dr. W. E. Fothergill read a paper entitled "Some Personal Impressions on Puerperal Eclampsia." He condemned the induction of labour as a routine practice in such cases and stated that in many cases it probably produced a fatal issue.

IPSWICH CLINICAL SOCIETY.—A meeting of this society was held at the East Suffolk Hospital on March 12th, Dr. W. W. Sinclair, the President, being in the chair.—The President showed two eye cases: (1) a case of Cataract complicated with extensive iritic adhesions operated on successfully; and (2) a case of Congenital Ptosis with associated movements of the affected eyelid.—Dr. H. H. Brown showed a case of Locomotor Ataxy with a Charcot's Knee. He then read notes on a case of Intestinal Obstruction in a child where a preliminary colotomy was performed and subsequently a large portion of gut was successfully resected. He also read notes on a case of Stricture of the Œsophagus due to the patient swallowing a mineral acid; gastrostomy was performed and the patient was now well.—Mr. J. F. C. Hossack read notes on some cases of Influenza complicated with Jaundice.—Mr. A. T. Pringle read notes on a case of removal of the Sigmoid Flexure for Carcinoma; the patient was doing well.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—At a meeting of this society on March 25th Dr. J. Nigel Stark, who was in the chair, read a paper on Ovariotomy in a patient suffering from Exophthalmic Goitre. In the case reported the symptoms of Graves's disease were very well marked and the tachycardia was excessive. Operation had to be resorted to. The therapeutic exhibition of thyroid had been detrimental. At the operation the tumour, which extended to the stomach, was partly gangrenous from twisting of its pedicle. The acute onset of the

was much relieved by the operation but succumbed on the second day. The heart-rate was then varying between 160 and 200 per minute. Dr. Stark thought that the condition had really been aggravated by the administration of the thyroid and he strongly advised that before operation on such cases the general condition should be improved. He recommended the administration of strychnia and perhaps digitalis some time before operation.—Dr. Edgar then reported four cases where Labour had been obstructed by Tumours in the Pelvis.—In the absence of Dr. Munro Kerr Dr. Russell gave a short outline of a case where Labour had been obstructed by a Myoma. Vaginal cœliotomy had been successfully performed.

Reviews and Notices of Books.

A Manual of Family Medicine and Hygiene for India. By SIR WILLIAM MOORE, K.C.I.E. Seventh edition. Revised by Major J. H. TULL WALSH, I.M.S. London: J. and A. Churchill. 1903. Pp. 680. Price 12s.

THIS book is intended neither for educational nor for technical purposes and is not meant to take the place of medical assistance and advice, but is offered as a substitute where such aid is not obtainable and as a means by which improper treatment may be avoided. It will be remembered that the origin of this work was the offer of a prize by the Government of India for a manual suitable for the numerous individuals necessarily scattered over India in positions more or less remote from medical and surgical aid.

Much care and attention have evidently been bestowed by the reviser on the present edition; he has endeavoured to bring each section up to date as regards the causation, symptoms, and treatment of the diseases dealt with and yet we doubt if the utility of this issue will be as great as that of its predecessors. Major Walsh has introduced scientific terms into the book instead of describing medical matters in "popular language" as had been done in the previous editions, and here we venture to think that he has made a very serious mistake. In our experience this work has been hitherto chiefly used by the less well-to-do class of Europeans and by the Eurasian population in India and especially by the female and less well-educated portion of this population, and we think that the introduction of scientific terms and of the skilled treatment often advised distinctly detracts from its usefulness. Many of the suggestions made require medical education for their comprehension and much of the treatment we can only call dangerous when removed from the hands of a properly qualified medical man.

In our opinion a book has passed beyond the side of safety and beyond the requirements of the non-medical public which recommends the testings of his secretions by a sufferer, the passing of catheters in retention, and the injection of diphtheria antitoxin with sterilised hypodermic syringes; which advises the puncture of the drum in inflammation of the middle ear; which prescribes large doses of opium, strychnine, nitrite of amyl, and other poisons; which expects a layman to detect the increase of resonance and the alteration in the breath sounds in emphysema; and which mentions that no attempt should be made by amateurs to syringe out the womb (p. 553). Nor do we think that writing of butyric and lactic acid dyspepsia and of the bacilli which cause the fermentations can serve any useful purpose.

429 pages of the volume are devoted to the description and treatment of various diseases and 130 pages to accidents, injuries, pregnancy, and labour. In the paragraphs on inflammation and abscess of the breast we miss the prophylactic treatment which might so usefully be dwelt on in a

book such as this; more also might be said of the open-air treatment of pulmonary tuberculosis and less of the medicinal; and under diseases of the lung we look in vain for a description or recommendation of the useful pneumonia-jacket. We do not think that the editor has noticed the most recent evidence as to the maximum incubation period in measles and we doubt if the recommendation to use the sulphates in inflamed piles will meet with much approval.

The description of the contents of the Indian medicine chest is excellent and very useful. We wish also to draw attention to the section on the Management and Feeding of the Infant and to Chapter VI. which treats of the Preservation of Health in India, a chapter which may be read with real advantage by all those going to India and in which young medical men embarking on an Indian career will find hints and information not to be found so readily elsewhere. Would that the directors of our great steamship companies could be so impressed with Major Walsh's remarks (p. 593) on the subject of the accommodation for sick passengers as to make improvements. What can be more painful than to see the sufferings of debilitated patients on board ship? Hospital cabins with extra attendance and a good and suitable cookery would be the greatest boon to helpless invalids, especially when suffering from diseases of the bowel and lung. As Major Walsh writes, "Such invalids ought to be in a cabin alone, not only for their own sake, but for that of others."

Chapter VII.—the Management of the Sick-room—in which its appearance, aspect, cleanliness, conservancy, deodorisation and disinfection, and many other points are discussed—is a very useful one, and the suggestions for "dietetic preparations" for invalids are clear and simple.

The book is printed in clear type, is well bound, and is a [illegible]fortable one to hold. More care might have been taken [illegible]oof correction—even on the first page there is a printer's [illegible] in the heading of the chapter, and "he skin" at 183 reads curiously.

The [illegible] Medical Treatment of Children in I[illegible] [illegible] A. BIRCH, M.D. Brux. Fourth edition, revised and enlarged. Calcutta: Thacker, Spink, and Co. London: W. Thacker and Co. 1902. Pp. 498, crown 8vo. Price 10*s.* 6*d.*

IN this new edition the high character and usefulness of this work are both well maintained. The author states that circumstances would have prevented him from preparing this new edition but for the assistance he has received from his friend, Dr. E. H. Young of Okehampton, who placed his large experience and such spare time as a busy practice permitted ungrudgingly at his disposal. With Dr. Young's assistance and the free access to his extensive library every page of the work has been carefully considered. The first edition of the book appeared in 1879 when Dr. Birch was asked by the publishers to re-write "Goodeve's Hints for the Management of Children in India," and its object was to instruct as to the rearing of children in India and to enable the parents to meet the emergencies incidental to child-life in that country without supplanting professional advice. When, seven years later, a second edition was called for, Professor D. B. Smith and Professor de Chaumont of the Army Medical School, Netley, went through the whole of the text and made various suggestions which were acted on. The third edition (1894) brought forth many important alterations and some additions and Dr. Birch more than ever tried to convey "a simple idea of the principles which should guide the rearing of children in India and the management of their maladies in that country, feeling convinced that the mere enumeration of sets of symptoms and treatments is unsatisfactory, puzzling, and unpractical." The present issue is divided into four parts which deal successively with the Management of the European Child in Health in India, the Nature, Mode of Spreading, Prevention and Detection of the Illnesses of European Children in India, the Management of the European Child in Sickness in India, and the Administration and Application of Remedies to Children.

Each of the 59 chapters may be studied with benefit. But may we suggest that in a future edition those on fractures and accidents may well be extended so as to embrace all the points which are brought out in the useful "First Aid" manual published and used by the St. John Ambulance Association? The chapter on the examination of sick children is a valuable one and is full of hints enabling parents to study and to understand their children's varying conditions; that on convulsions is also much to be commended. Chapter XVI. deals largely with the reduction of the excessive heat of the body in fevers and we are glad to note the stress which is laid on the worth of the cold bath and the use of the wet pack and of oil friction, the latter being a proceeding the value of which is well known to the natives. The hints on the administration of remedies are very practical and the medicines recommended are such as can be easily prepared.

After very carefully perusing the book we feel that we can unhesitatingly recommend it. It is most clearly written; the advice is not only sound and such as is capable of being carried out by any mother of average intelligence, but the volume is also replete with useful information from cover to cover, and due caution is always observed when drugs which might possibly have untoward effects are recommended. The edition is not only a distinct advance on the last issue, but it is brought thoroughly up to date, and we hope that it may find its place in many homesteads which children make glad in India and the far East.

The Treatment of Tabetic Ataxia by Means of Systematic Exercise. By Dr. H. S. FRENKEL, Medical Superintendent of the Sanatorium "Freihof" in Heiden (Switzerland). Translated and edited by Dr. L. FREYBERGER, M.R.C.P. Lond., Honorary Physician to the St. Pancras and Northern Dispensary; the Pathologist to the Great Northern Central Hospital. With 132 Illustrations. London: Rebman, Limited. 1902. Pp. 185. Price 12*s.* 6*d.* net.

THIS volume is intended to be an exposition of the principles and practice of the "compensatory movement treatment" of tabetic ataxia. Dr. Frenkel's method of treating this disease by systematic and graduated exercise does not claim to influence the tabetic process itself, but to exert a beneficial effect on the most prominent symptom—the ataxia. Since this method of treatment was first introduced it has been improved and simplified. Dr. Frenkel's method of treating tabetic ataxia differs from that associated with the names of Professor von Leyden and Professor Goldscheider in two important points: it lays the greatest stress on the careful repetition of movements and not on athletic strengthening of muscles and, secondly, it requires very little apparatus.

The first part of the work gives an account of the symptoms and various types of tabetic ataxia, but the main part of the volume is occupied with a minute description of the movements and exercises employed by Dr. Frenkel in his particular method of treatment. This description is somewhat difficult to follow, as must necessarily be the case when expressing certain movements in words, more particularly as the exercises are very numerous. This difficulty is, to some extent, overcome by an excellent series of reproductions of photographs and diagrams. Doubtless the exercises could be learned by practical demonstration in a fraction of the time which would be occupied by attempting to follow them from a written description, and we can only express our opinion that Dr. Frenkel has been but partially successful in explaining his methods by the publication of this work.

LIBRARY TABLE.

Artificial Infiltration Basins for Potable Water. By J. GUST RICHERT. London: Hodgetts, Limited.—Mr. J. Gust Richert of Stockholm has republished in pamphlet form a paper recommending the more general use of artificial infiltration basins for the preparation of water for domestic supplies. The essence of the system is to make use of the soil for the purification of the water and three ways are mentioned in which this method is now practically used: (1) filtration through a porous river bed; (2) irrigation, similar to that used for the purification of sewage; and (3) irrigation basins possessing surfaces which can be cleansed. The use of the first of these methods is open to more than one objection and it is not likely that its use will be generally adopted in this country. The results obtained in France are deterrent. Nor does the second method possess any advantages over the system of purification by sedimentation and filtration which usually can be easily applied to upland waters. The use of cleansible infiltration basins, which is the plan adopted at the Gothenburg waterworks, might probably be utilised with advantage in some rural districts in this country. The system is really one of great simplicity. The reservoir, a basin, is lined with sand through which the water penetrates and then passes for some considerable distance through the ground. The surface of the sand requires cleaning at intervals in the usual manner and it is therefore necessary that at least two infiltration reservoirs should be provided. The water is purified by its passage through the sand and the soil and its temperature is lowered in summer and raised in winter in the course of its transit, so that by this means the water obtained in the collecting pipe is pretty constant in temperature. It is evident that only certain localities are suitable for such a system as that which has been briefly described. The ground itself must be free from poisonous matter and from animal pollution and a considerable area is required. When all these conditions are present the system is not without its advantages, the chief of which perhaps is the uniformity of the temperature of the water. For these reasons we have thought it worth while to call the attention of those interested in rural water-supplies to the question. The chief object of Mr. Richert's paper apparently is to advocate this system for the water-supply of London—a purpose for which it would be unsuitable for many reasons which it is not necessary to mention.

Massage and the Swedish Movements. By KURRE W. OSTROM. Fifth edition. London: H. K. Lewis. 1902. Pp. viii.-181. Price 3*s.* 6*d.* net.—This is a useful little book upon massage and Swedish movements which when employed in the right way are admirable adjuncts to ordinary medical treatment. Mr. Ostrom, we are glad to see, is very strong upon the point that massage ought to be fully controlled by the medical profession as it is in Europe. He is writing of massage as he found it in the United States of America where quacks of all kinds flourish in an even more brazen-faced manner than they do in England, but whatever may be the case in other European countries we are sorry to say that massage in this country is not fully controlled by the medical profession. Mr. Ostrom considers that massage and movement treatments should only be applied by educated and properly trained persons, with due regard to the physician's directions—an opinion with which we quite agree.

Burdett's Official Nursing Directory. Fifth year. London: The Scientific Press, Limited. 1903. Pp. 439. Price 3*s.* net.—This the fifth annual edition of Sir Henry Burdett's useful Directory differs from that of last year in that a list of institutions supplying trained nurses for private cases has been added. This list, which will be found of value to practitioners, gives particulars of the number of nurses employed, the charges made for their services, and, in some cases, of the length of training required by the institution in question. The other features of the work remain the same as in last year's issue.

A Historical Companion to Hymns Ancient and Modern. Edited by the Rev. ROBERT MAUDE MOORSOM. Second edition. London: C. J. Clay. 1903. Pp. xxvii.-380. Price 5*s.* net.—We feel some diffidence in reviewing this work, for hymnology and medical science are at more or less opposite poles. But still Sir Thomas Browne wrote a real hymn, we mean his "dormitive" which was closely modelled on two hymns from the Sarum Breviary, while Henry Vaughan, also a medical man, has given us a number of devotional poems some of which are extremely beautiful, although they are perhaps not hymns in the sense of being rhythmical compositions fit for use in public worship. Mr. Moorsom's little book will bring home to those who read it how much the English Church owes to the compilers of "Hymns Ancient and Modern." It will also show how inferior are most modern hymns to ancient ones. We mean as regards their use in the public worship of the church, for as a rule they are all subjective. Of course, there are some fine modern hymns, notably Newman's "Praise to the Holiest in the Height" and Watts's "Jesus shall reign where'er the sun," and this last is mainly a paraphrase of Psalm lxxii. Mr. Moorsom's book is very interesting, and we only hope that the forthcoming edition of "Hymns Ancient and Modern" will be found to have taken note of some of his suggestions for a "Book of Common Praise."

Disinfectants and Antiseptics: How to Use Them. By EDWARD T. WILSON, M.B. Oxon., F.R.C.P. Lond. Fortieth thousand. London: H. K. Lewis. A folding card. Price 1*s.* per dozen.—This card of directions for the domestic use of disinfectants and antiseptics contains much that ought to be kept in mind by heads of families and the public in general and the essentials of the subject are explained in a plain and easy style. Hot air, hot water, and steam naturally hold the first place in the treatment of infected clothing or other articles of personal use. A variety of chemical disinfectants are also enumerated, including carbolic acid, chloride of lime, formic aldehyde, corrosive sublimate, Condy's fluid, and sulphurous acid. With regard to this last-named substance it is almost a pity that Dr. Wilson after recommending the burning of brimstone or sulphur candles, should go on to speak of cylinders containing the compressed gas, for these require more careful management than is to be expected from an ordinary householder. Condy's fluid is essentially a permanganate of sodium and not of potassium, a point to which we have already referred in THE LANCET of Dec. 1st, 1900, p. 1587.

Applied Religion. By W. WINSLOW HALL. London: R. Brimley Johnson. 1902. Pp. 143. Price 3*s.* 6*d.*—This book is divided into four sections which deal respectively with (1) Personal Applied Religion; (2) Social Applied Religion; (3) National Applied Religion; and (4) International Applied Religion. It contains also a proem and epilogue in verse and four hymns and four sonnets, one of each of which is devoted to each of the divisions of the book. The title "Applied" Religion is reminiscent of the same word used in connexion with mathematics or to one of the other exact sciences and its occurrence in the present connexion seems rather to imply that religion itself is not in its nature practical. The author of the book appears to be an original thinker and incidentally gives a form of prayer which may "suit some" as an alternative for the Lord's Prayer, while he explains with great clearness texts of scripture which have given rise to much difference of opinion amongst theologians. The book has presumably been sent for our criticism because the author has a special message for members of the medical profession. He criticises the dress normally worn by them in his article on Applied Religion in regard to Clothing, and in his practical notes he gives an example of what dress should be worn by practitioners who possess the true faith. The strictly proper "medic," while he is working for his bread and grappling with disease and death, usually handicaps himself with a load of dingy, hampering, and complex "casements." Let these be contrasted with the dress of the middle-aged London "medic" who, we are pleased to learn, finds it easy to earn his living. This gentleman wears next the skin a single layer of cellular cotton with collar and cuffs of the same material, a loose jacket, vest, and trousers of serge, thin socks, "tan shoes," and a soft, well-perforated, felt hat. The diet of the same observer is also apparently given as an example of applied religious life. He breakfasts at 8 o'clock on oatmeal porridge and milk, one biscuit of pure protene, one and a half slices of bread with butter or jam, and two cups of "swiltzer" as adjuncts. His lunch consists of bread and cheese, with butter, jam, or fruit "as adjuncts." In the afternoon he has two cups of weak tea and he dines at 7 o'clock "off" cheese, protene biscuits, with potato or other vegetables and olive oil, some milk or suet pudding, and occasionally some fruit. One of the sonnets in the book is devoted to the censure of excessive eating and opens with the lines:—

> "Weird oneness! not a mouthful in excess
> But venoms me and hungers haggard poor."

The keynote to the epilogue is given by the first line, "Gabgabble not! do it!" This mysterious command, if we read it aright, is one that can be very well laid upon most persons who possess elaborate rules of living. By all means let the man with views about his clothing, his diet, and his creed put on what he likes, eat what he likes, and believe what he likes. But when he starts out as proselytiser let him be very certain that what he has to say is for the genuine good of his generation lest that generation turn round on him and forbid him to "gabgabble."

JOURNALS AND MAGAZINES.

The Practitioner.—Mr. W. Arbuthnot Lane is always interesting in his writings upon fracture—and generally iconoclastic. His contribution on the Mode of Production of Fractures of the Lower Extremity by Indirect Violence in the March number of the *Practitioner* forms no exception to the rule. Commonly accepted theories repeated from text-book to text-book and from generation to generation, the idols of succeeding series of examinees, are subjected to the searching investigation of Mr. Lane's science and are hurled to the ground. His article is accompanied by some excellent reproductions of skiagrams. Dr. Herbert S. French provides an instructive article upon Examination of the Blood, with some striking examples showing its wide range of value in settling diagnostic difficulties in certain cases. A case of double pyosalpinx, at first regarded as typhoid fever and recognised with certainty as deep-seated suppuration mainly by a blood count, is particularly valuable. Similarly the value of unusual prevalence of coarsely granular eosinophile cells comes out strongly in a case where the diagnosis hesitated between asthma and intra-thoracic tumour Other shorter original articles and a careful review of recent work on disease of the liver, by Dr. Rolleston, combine with the editorial notes to make a capital number of the journal.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, K.C.B., F.R.S., and J. N. LANGLEY, Sc.D., F.R.S. Vol. XXIX., No. 2. March 16th, 1903. London: C. J. Clay and Sons. *Price 7s.*—*The articles contained in this number of the Journal of Physiology are the following*:—1. Contributions to the Physiology of the Lungs, Part I., The Bronchial Muscles, their Innervation and the Action of Drugs upon them. The authors of this article have been able to construct and to apply an oncometer to a lobe of the lung and to determine the changes in its volume during its movements in normal and artificial respiration. The text is illustrated by many tracings. It is shown amongst other points that the broncho-constrictor fibres run in the vagus, as do also the broncho-dilator fibres, and that the latter are particularly well developed in the cat. The sympathetic contains no broncho-dilator fibres. The action of many drugs is described. The article is a long and valuable one. 2. On the Uniformity of the Pancreatic Mechanism in Vertebrata, by W. M. Baylis and E. H. Starling. The authors of this article maintain that the secretion of pancreatic juice is excited in all the vertebrata by the action of an acid leading to the production of a substance named secretin in the epithelial cells of the intestinal mucous membrane. This substance is at once absorbed into the blood-vessels and is carried by the blood to the pancreas, on the cells of which gland it acts as a specific stimulus. 3. The Estimation of Urea in Blood, by Joseph Barcroft. The essential point of this article is that the globulins and other proteids are removed by precipitation with alcohol and subsequently by the employment of sodium hypobromite. 4. Remarks on the Dorsal Spino-cerebellar Tract, by C. S. Sherrington and E. E. Laslett. 5. Further Observations upon the Respiratory Exchange and Temperature of Hibernating Animals, by M. S. Pembrey. These observations have been made upon dormice and hedgehogs. The temperature of a dormouse awaking from torpidity may rise as rapidly as 19° in 42 minutes, the respiratory exchange is greatly increased, and the respiratory quotient rises to 0·75. The temperature of a hedgehog waking from its winter sleep may rise 20° in 120 minutes. The respiratory exchange is greatly increased; it may be 30 or 40 times as great as that of the torpid animal. The respiratory quotient rises to 0·78.

New Inventions.

APPARATUS FOR THE OPEN ADMINISTRATION OF NITROUS OXIDE GAS.

SINCE I first drew attention to the practicability of administering nitrous oxide *openly*[1] I have been endeavouring to make the process more simple and to devise more suitable apparatus. My aim has been to enable this system of administration to be carried out in positions of the patient's face other than those permitted by the face-pieces shown in THE LANCET of Feb. 4th, 1899, and at the same time to facilitate the suitable delivery of the gas.

For convenience of description the apparatus requisite for open administration may be regarded as consisting of two entirely distinct portions, each with its own definite function —viz., (1) the appliances by which the discharge of the nitrous oxide gas can be at will controlled; and (2) a special facepiece or inhaler for receiving and guiding the gas and air to the patient; in short, a delivery apparatus and an *open* inhaler. In the same manner the duties of the administrator are twofold; on the one hand he must regulate and control the supply of the gas by means of the delivery apparatus, and on the other he must see that the gas is safely conducted to the patient by means of the inhaler. The delivery apparatus may be a mere tube leading from a gasometer or an elaborate arrangement of cylinders and brasswork; whatever type one proposes to work with should be capable of very rapid and smooth control and should be silent in its action. The employment of a bag is a convenience rather than a necessity; it assists in breaking the force of any unduly violent escape of gas; it also serves as a guide to the administrator, for by observing the degree of expansion caused by each fresh discharge *from the cylinders it is easy to estimate the* amount of overflow taking place into the inhaler. With a *reliable* delivery apparatus the discharge of gas can be regulated very accurately and the expenditure kept within very small limits. The employment of large gas-bags tends both to waste and to irregularity of delivery, for it is not so easy to increase rapidly, or to check suddenly, the flow of gas from the mouth of a large bag into the inhaler as it is from a small one. A bag of about one gallon capacity is in my [illegible] The tube leading from the [illegible] not be attached to the dist[illegible] bag but be led into its proximal end or mouth (i e., close to the inhaler), the bag hanging free (see illustration, B, D), so that the drag of the heavy indiarubber tube upon it may be avoided; in open administration the weight of the tube when attached to the fundus of the bag is very liable to hamper materially the smooth delivery, particularly when the head of the patient is in an awkward position or at the extreme stretch of the apparatus.

---

[1] THE LANCET, Oct. 8th, 1898, p. 933, and Feb. 4th, 1899, p. 295.

FIG. 1. FIG. 2.

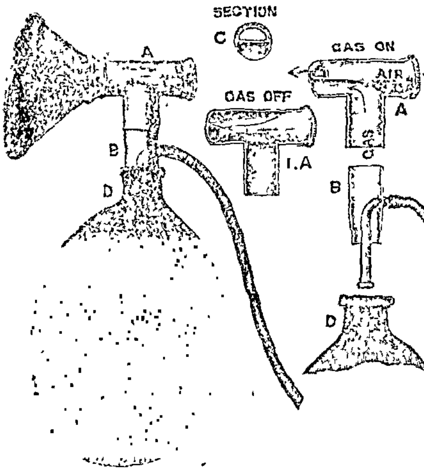

Fig. 1 shows a simple arrangement for filling an open cup-shaped inhaler. Fig. 2 shows an open stop-cock and attachments, in section.

The mouth of the gas-bag can be most conveniently opened or shut by means of the open stopcock (A), devised by myself. It is formed of a T-shaped tube, the upright portion of which is connected with the bag, and one end of the crosspiece with the inhaler Into the crosspiece is telescoped a specially shaped inner tube, which fits the *outer* closely at *one* end, but is flattened obliquely at the other towards the facepiece (as indicated in the diagram) so that there it merely occupies half the lumen of the outer (C). The effect of this is that in one position ("Gas on" in diagram) a double tube is produced for the admission simultaneously of gas and air; but by turning the inner tube round ("Gas off" in diagram) connexion with the bag is shut off so that the further admission of gas is prevented. This stopcock can be inserted into the top of an ordinary facepiece, and as it is open at both ends this will constitute a form of open inhaler. It is made entirely of metal, and as it contains no valves or other mechanisms, cannot get out of order without great violence, and may be cleaned and boiled as frequently as desired. Whatever form of inhaler be employed it must be made of gas-tight material and of such a shape that it can be accurately adapted to the patient's face and thus prevent leakage from below, whilst its sides should be sufficiently high to prevent loss from overflow. It will be observed from the foregoing that the administrator merely controls the supply of gas and insures its delivery to the patient, the air does not need management. Should the effects produced upon the patient not be commensurate with the quantity of gas employed it will almost invariably be found that the patient is not actually receiving the gas in consequence of the faulty application of the inhaler to the patient's face. At the commencement of an administration the delivery of the gas should be moderately free, but always gentle, the volume provided for each breath being gradually increased until the patient appears to be passing under its influence, when the supply should be reduced.

The open system of administration can be applied *viâ* the nose, the mouth, or through a tracheotomy tube with equal facility. Through the nose it is most conveniently carried out by means of an open stopcock fitted to a specially shaped nasal inhaler which accurately fits the patient's face, so that the nares remain in direct communication with the surrounding air through the permanently open central tube of the stopcock. *During the inhalation of the nitrous oxide it is not necessary to cover the mouth.* Although I have frequently demonstrated the feasibility of administering gas openly through the nose, it is only recently that I have made any serious attempt to apply the system in this manner. The effects appear to be identical with those produced when the gas is inhaled through any other channel, with one exception—viz., that the resulting anæsthesia appears to be produced with greater rapidity, frequently within 15 seconds, and that it can be maintained with a very small additional *expenditure of gas and independently of any intercurrent* mouth-breathing. The patients recover as rapidly after a ten minutes' administration as after an administration lasting only a single minute. They are never cyanosed and do not experience any unpleasant after-effects. I have employed the open method of administration on considerably over 5000 individu[illegible] that it is sound, useful, [illegible] of cases. The various forms of apparatus have been made for me by Mr. J. H. Montague, 101, New Bond-street, London

GEORGE B. FLUX, M.D. Brux., M.R.C.S. Eng.,

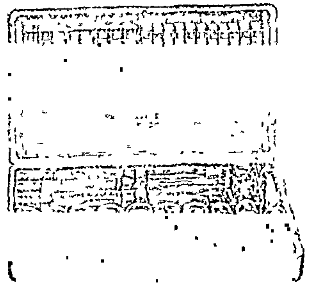
Old Burlington street, W.

A POCKET EMERGENCY CASE.

THE pocket case shown in the illustration enables the practitioner to carry in a convenient form the drugs that are most likely to be required in an ordinary emergency and in country places will often save him the necessity of returning home during the visiting round for the purpose of making up some particular draught. The selection of drugs for filling the case may, of course, be varied according to individual taste. The stock that I carry consists of 12 varieties of hypodermics (morphia, cocaine, atropine, pilocarpine, ergotinine, &c), seven varieties of tablet triturates, three varieties of compressed tablets, and six varieties of chocolate-coated tablets named respectively "active cathartic," "migraine," "creasote compound," "opium," "rheumatic," and "cascara" I also take a hypodermic syringe, two needles, one exploring needle, a tube of Schimmel's needles, drachm bottles of ether and of distilled water, and a pipette for eye



not to waste time as the arm must go. They hesitated to amputate, however, in view of the comminuted fracture till Professor Bassini should arrive from Padua; and so they watched all night by his bedside, relieving each other by twos. On the next morning, the 26th, Professor Bassini joined them and after a long examination of the wound, conducted by the patient's desire without anæsthesia, he coincided with his Florentine brethren that amputation should not be performed as, among other reasons, the warmth of the right hand proved that the circulation was being restored. Professor Bassini thereafter returned to Padua, leaving his intrepid patient in the hands of his colleagues who are now beginning to hope that the arm may be saved, though, it is feared, never likely to be available for the splendid work associated with the name of Colzi. The scene at the hospital all this time has been inexpressibly touching, patient after patient in all stages of cure or convalescence importuning the official staff for news of their beloved benefactor, while the King is kept informed by His Majesty's express desire of the professor's condition. As I write the latest bulletin has been handed in to me, dated 9 A.M.: 'Tranquil night. The general state is good. The conditions of the limb are unchanged.' Professor Colzi, I may add, is only in his fiftieth year, having being born at Monsummano barely half a century ago. His record in the radical cure of hernia is unequalled in Italy and scarcely surpassed in Europe, while in other departments of surgical intervention his reputation stands exceptionally high."

THE PATHOLOGICAL CHANGES ACCOMPANYING TRIGEMINAL NEURALGIA.

IN the *Journal of Nervous and Mental Disease* for February Dr. Sidney Schwab gives an account of the systematic study of six Gasserian ganglia which had at various times been excised in cases of severe and intractable facial neuralgia. In three of the cases the ganglia were removed before any peripheral operation, such as excision, had been performed on the branches of the trigeminal nerve. All these specimens were fixed and hardened while fresh and sections were prepared according to the latest methods, including Nissl's and Held's methods, which are in use for revealing changes in nerve cells and nerve tissues generally. Complete serial sections were made of every ganglion parallel to the largest diameter. The following were the typical changes found in these six cases. The nerve cells in the peripheral parts of the Gasserian ganglion showed changes varying from a slight degree of chromatolysis to profound changes of total cell disintegration and nuclear migration. In three of the six ganglia pigmentation was observed around the nuclei of the nerve cells. This pigmentation was so different in character and distribution from that present in normal conditions that it would be regarded, adds Dr. Schwab, as a deviation from the normal. In one of the ganglia a sclerosis of the tissue with excess of fibrous formation was found. In some of the ganglia neuritic changes were observed in the peripheral branches, but only in those cases in which a peripheral operation had previously been performed. Dr. Schwab points out that all of these ganglia "were cleanly removed" and given to him in a fresh state well adapted for histological study. They were all from cases of the most severe form of trigeminal neuralgia, and in three of them there had been no peripheral operation to complicate the microscopical findings. It therefore seemed a fair conclusion that, if trigeminal neuralgia depended upon disease of the Gasserian ganglion, these six ganglia would exhibit the pathological changes which were associated with the chief symptoms. The complete disappearance of the symptoms of neuralgia when the ganglion was removed or when the root which connected it with the brain was divided showed that the ganglion was the seat of the disease. Two explanations are offered as to the cause of the intense pain; first, that it was produced by an irritant or toxic agent circulating in the blood and having a selective action upon the nerve cells of the Gasserian ganglion; and, secondly, that local or mechanical causes, such as pressure on the ganglion and overgrowth of connective tissue within it, were the agencies. It was difficult to decide between these two sets of causes and it was probable, adds Dr. Schwab, that both played a part in causing trigeminal neuralgia, the toxic factor being the more important of the two. The nerve cells in the Gasserian ganglia exhibited in all cases signs and changes indicative of prolonged irritation and over-stimulation, in some respects closely resembling the appearances produced (artificially) by electric stimulation for several hours. As to the nature of the toxic or other agency which produces such pathological irritation of the cells, adds Dr. Schwab, we are still in ignorance, but the results of investigation have shown that the locus of the disease is in the Gasserian ganglion and that the agency is a toxic or irritant substance. The ground for future inquiry is thus narrowed and the tracing of the agency in question should therefore be practicable.

THE DISTRIBUTION OF PLAGUE.

AS regards the Cape Colony, the medical officer of health of the colony reports that for the week ending March 7th the state of plague at the various places in the colony was as follows: At Port of Table Bay 1 Indian male adult, a member of the crew of the s.s. *Nevasa* which arrived in Table Bay on March 3rd from Bombay and Eastern African ports, died suddenly from plague on board that vessel in Table Bay on March 6th. The rats on board this vessel have been found to be infected with plague. At Port Elizabeth 11 cases of plague were discovered during the week ended March 7th—namely, 1 European male, 6 coloured males (2 of whom were found dead), 3 coloured females, and 1 native male. The cases were discovered on the following dates—namely, 3 on March 1st, 2 on the 2nd, 2 on the 3rd, 1 on the 4th, 2 on the 5th, and 1 on the 6th. At the plague hospital, Port Elizabeth, 2 coloured male patients died during the week, leaving 23 cases still under treatment. Plague-infected rats continued to be found in different parts of the town. A mortality among rats is occurring at East London at the wharves on the east bank of the Buffalo river. Certain of the dead rats have been proved to have died from plague. During the week ended March 7th 4 cases of plague were reported at King William's Town, 2 being adult male Europeans and 2 being adult male natives. Of the latter, 1 died on March 6th; the remaining 3 cases were isolated in the plague hospital. Plague-infected rats continued to be found at Graaf-Reinet during the week and a death suspicious of plague occurred in the person of a European adult female.

THE SUBJECTIVE SYMPTOMS OF TABES DORSALIS.

Professor Joseph Collins of the New York Post-Graduate Medical School has published in the *Medical News* of March 7th a paper dealing with the subjective symptoms of tabes dorsalis, based upon a study of 140 cases of the disease. An account of Professor Collins's observations on the objective symptoms of tabes, based on a study of the same number of cases, appeared earlier in the year and was then referred to in THE LANCET.[1] The subjective symptoms of tabes, says Professor Collins, are variable, the objective symptoms are constant. The former, however, comprised a number of important conditions as ascertained by the study of the above 140 cases. Pain in the lower extremities was one of the most constant symptoms. The pain was usually "shooting" or "lightning-like" in character, and less frequently it was described as "tearing" or "burning." Intensely painful spots were also found on the limbs. All these pains of tabes may be accompanied, adds Professor Collins, by violent contraction of the painful part. Next in importance were crises or attacks of suffering and distress felt in the stomach, the bladder, the rectum, and the larynx. Paræsthesiæ of the extremities, such as numbness, tingling, formication, "pins and needles," and a feeling as of the skin being "tightened," were also common. Vertiginous sensations were frequent, especially when the patient was in an unaccustomed place. The remaining subjective symptoms of tabes comprised lessened sexual desire and a feeling of inability to expel urine freely from the bladder. Professor Collins concludes by giving a classification of tabes into "types" for clinical and prognostic purposes. These comprise a neuralgic type with pains of great severity as the main symptom, a visceral and trophic type with visceral "crises" and joint disease, a markedly ataxic type in which the patient becomes rapidly helpless and bedridden, a cerebral type in which optic atrophy appears early, a cervical type in which the upper limbs are chiefly involved, a benign type in which the progress of the illness is very slow, a "galloping" type the course of which is rapid, and a mental type which tends to dementia. The prognosis varies with the type of the disease.

---

OBSERVATIONS UPON LONG-DISTANCE RUNNERS.

THE *Boston Medical and Surgical Journal* of Feb. 19th contains an interesting series of papers on observations upon long-distance runners which are edited by Dr. J. B. Blake and Dr. R. C. Larrabbee. The Boston Athletic Association holds an annual "Marathon race"—i.e., a foot-race with a course equal to the distance from the battlefield of Marathon to the Stadium in Athens—about 24 miles. The following are the results of a large number of careful observations made after the races of 1900, 1901, and 1902. After the race the pulse was always increased but the increase was often surprisingly small. It was least in the best-trained men and in those who finished slowly. Rates varying from 82 to 180 were recorded. Moderate irregularity was not infrequent. The tension was very low and dicrotism was sometimes present. In cases of severe fatigue there was a small "thread-like" pulse. The competitors lost weight to the extent of from 3 to 6 pounds. The temperature in the mouth was sometimes raised, often normal, and occasionally subnormal. But the rectal temperature was almost invariably raised and varied from 100° to 104° F. The variability of the temperature in the mouth is explained by the mouth-breathing which all violent exertion causes. The difference between the oral and rectal temperatures was often as great as 7°. Examination of the blood showed invariably a leucocytosis which varied between 14,200 and 27,700. The greatest increase was in the polymorphonuclear leucocytes. The percentage of large forms as compared with small ones was invariably increased Eosinophiles were decreased, both absolutely and relatively. In seven out of nine cases a few myelocytes were found. The leucocytosis was thus of the inflammatory type (in which the increase is wholly or mainly in the polymorphonuclear neutrophiles), in contra-distinction to the physiological leucocytosis observed during digestion and pregnancy and after moderate exercise, cold baths, or massage (in which the percentage of the different varieties of leucocytes remains unaltered). Before the race the heart was invariably found to be enlarged; this was due mainly or wholly to hypertrophy the result of training. After the race there was slight further enlargement which was inferred to be the result of acute dilatation. In some cases murmurs were heard before the race and were thought to be due to excitement. Murmurs also developed during the race. Thus of nine cases in which no murmur was heard before the race murmurs were heard after it in six. Of these murmurs three were cardio-respiratory, ceasing on holding the breath. The other three were apical systolic. Whether they were due to temporary mitral regurgitation from relaxation of the mitral orifice could not be determined. The changes in the urine are of great interest. The colour was always higher than before the race; often the urine was slightly turbid and sometimes it was smoky. The acidity was markedly increased. The changes in the specific gravity were inconstant; in the majority of cases it was diminished. The amount of urea excreted in the 24 hours after the race was not increased; on the contrary, it was sometimes diminished. These results are in accordance with the researches made by Fink and Wislicenus in their ascent of Faulhorn and with the later work of Voit and Parkes. The excretion of uric acid appeared to be diminished in the majority of cases. The chlorides were constantly diminished to the extent of about 50 per cent. A trace of albumin was invariably present and persisted in most cases for at least 36 hours. All the sediments contained large numbers of hyaline and finely granular casts and a few coarsely granular and epithelial casts. Blood was always present—free and on the casts. Brown granular casts were rarely found. Calcium oxalate crystals were present in most cases. Spermatozoa were observed in several cases.

SMALL-POX AND THE CORPORATION OF DUBLIN.

IN THE LANCET of March 28th, p. 905, we mentioned that an outbreak of small-pox had occurred in Dublin. The public health committee, with an activity which is worthy of praise, took steps to limit the severity of the outbreak by a system of isolation, of removing "contacts," and of vaccinating them. Unfortunately, however, the zeal of the public health committee was like that attributed to the Jews by the Apostle Paul—namely, zeal not according to knowledge. At the meeting of the North Dublin board of guardians held on March 25th and reported in the *Dublin Telegraph* of that date a report was read from Mr. David Fagan. This report stated that Mr. Fagan had been informed that various persons since they had been discharged from the Dublin Corporation Refuge, whither they had been taken while their rooms, clothing, and the like were being disinfected, had had no food. No one would give them work and the guardians of the poor said that they could not grant relief, for that it was the duty of the corporation to do so. Mr. Fagan managed to give them food and firing on his own responsibility. This state of things is bad enough, but it is as nothing compared to the treatment which the unhappy "contacts" received in the refuge. From a sworn statement made before Mr. W. L. Kenny, K.C., deputy divisional magistrate, which sworn statement was incorporated in Mr. Fagan's report, we learn that the deponent, a man, together with his wife and an infant, aged six days, were removed to the refuge on March 7th. Their clothing was all taken away. The deponent, his wife, and the baby were allotted one room; in the three other rooms were huddled together over 40 persons, members of 11 families. The only clothing they had was a blanket taken from the bed. Men, women, and children were all mixed up together in this practically nude state, and deponent said that he saw a girl go down to the kitchen to be vaccinated with nothing on but a blanket. Men walked about the rooms completely naked and drunk. The guardians considered that the matter should be referred to the Local Government Board. If these statements are true we have no hesitation in saying that the matter is an absolute and crying disgrace to all concerned. We say, "if they are true," for Sir Charles Cameron, the superintendent medical officer of health, declared on being interviewed that the statement was a gross exaggeration. He did not deny, however, that no clothing was given to the "contacts" to wear while their own rags were being disinfected, but he said that they had to remain in bed while the disinfection was proceeding. There also seems to be no doubt that many "contacts" got drunk, and Sir Charles Cameron allowed that they were supplied with wine, stout, and whisky. This we should call an error of judgment. Moreover, we think that the guardians were to blame for not seeing that the poor for whom they are responsible were supplied with food after leaving the place euphemistically called a "refuge." Segregation of "contacts" is a good thing, revaccination is also a good thing, but if the corporation of Dublin thinks that measures undertaken in the way that we have quoted, or even in the modified manner described by Sir Charles Cameron, will make people pay more attention to hygiene, will improve the status of the poor, or will make them value vaccination more highly, the sooner it is taught differently by as sharp measures as possible the better. We await with interest the action of the Local Government Board.

THE FUTURE OF ST. GEORGE'S HOSPITAL.

THE following fly-sheet is being circulated amongst the governors of St. George's Hospital:—

St. George's Hospital, S.W., March 26th, 1903.

The governors of St. George's Hospital who were present at the recent court held at Grosvenor House would appear to have carried away an erroneous impression to the effect that a large majority of the medical and surgical staff are in favour of the removal of the hospital *under any circumstances. The undersigned members of the staff wish to* state that this is not the case and that they are not in favour of removing the hospital under any circumstances *unless* such a sum of money can be obtained for the present site as will suffice to build and equip a perfect modern hospital of not less than 360 beds on a suitable site; to build and equip a thoroughly up-to-date medical school; to provide a nursing home; and to increase the endowment of the hospital sufficiently to meet all such additions to expenditure and all such loss of income as may be incurred by removal.

Failing these conditions they are in [illegible] deavour to raise sufficient money either (1) to [illegible] present site and such land as may be obtain[illegible]ghbourhood; or (2) to purchase such adjoining land as may be available and to bring the present buildings as far as possible into line with modern requirements.

(Signed)

Wm. Ewart, M.D., Senior Physician; F. G. Penrose, M.D., Physician; H. D. Rolleston, M.D., *Physician*; *Wyndham Cottle, M.D., Physician for Diseases of the Skin; F. W. Hewitt, M.D., Physician Anæsthetist; *Lee Dickinson, M.D., Senior Assistant Physician; Cyril Ogle, M.B., Assistant Physician; Arthur Latham, M.D., Assistant Physician and Dean of the Medical School; Arthur Stabb, M.D., Assistant Obstetric Physician; *G. R. Turner, F.R.C.S., Surgeon; A. Marmaduke Sheild, F.R.C.S., Surgeon; W. Adams Frost, F.R.C.S., Ophthalmic Surgeon; W. C. Bull, F.R.C.S., Aural Surgeon; Herbert W. Allingham, F.R.C.S., Senior Assistant Surgeon; F. Jaffrey, F.R.C.S., Assistant Surgeon and Dean of the Medical School; Herbert S. Pendlebury, F.R.C.S., Assistant Surgeon; H. B. Grimsdale, F.R.C.S., Assistant Ophthalmic Surgeon; Norman G. Bennett, M.B., Assistant Dental Surgeon.

* These members are only in favour of the two last clauses.

At the present time the active medical and surgical staff of the hospital consists of 22 members, of whom 18 have now declared that unless an almost ideal set of conditions should prevail to alter their views they are not in favour of moving the hospital from its present site. This consensus of opinion cannot fail to be influential.

THE SALE OF POISONS.

WE have received a copy of a Bill which has been introduced into the House of Commons by Mr. Thomas Lough, M.P. for West Islington, and which is backed by Mr. John Burns, Mr. J. Henniker Heaton, and others. The objects of the Bill are good and may be shortly summarised as tending to check the abuses which are at present connected with the sale of poisons. The main point of the Bill is contained in the two following clauses:—

1. In this Act "*the society*" *shall* mean "the Pharmaceutical Society of Great Britain," "registered person" shall mean a "pharmaceutical chemist or a chemist and druggist," "poison" shall mean a poison within the meaning of the Pharmacy Act, 1868, "registrar" shall *mean the registrar of the society.*

2. From and after Dec. 31st, 1903, it shall be unlawful for any person or any company, firm, [illegible] persons to keep any open shop or shops fo[illegible] compounding of poisons or of medical [illegible] shall be *bonâ fide* conducted by a registered person, or to permit or suffer in such shop any poison to be retailed or any medical prescription to be retailed, dispensed, or compounded otherwise than by or under the supervision of a registered person; also it shall be unlawful for any person or any company, firm, co partnership, or body of persons to keep any such shop unless the address of the shop shall have been registered upon the register of shops to be kept under this Act and the name and address of the registered person to be in the *bonâ-fide* conduct of the shop shall have been registered upon the register of persons in the *bonâ-fide* conduct of shops to be kept under this Act, and also it shall be unlawful for any person or for any company, firm, co-partnership, or body of persons to sell or to negotiate or participate in the sale by retail of any poison at or upon any place other than an open shop registered upon the said register of shops.

3. The address of the registered shop whereat a sale of poison takes place shall be the address of the seller for the purpose of the labeling required by Section 17 of the Pharmacy Act, 1868.

We do not see, however, in this Bill as drafted any clause whereby the rights of medical men to dispense their own medicines, either themselves or through the agency of a qualified dispenser, are to be preserved and one should certainly be added. Moreover, we think that the provisions of the Pharmacy and Sale of Poisons Acts should no longer be able to be evaded, as they are now in the case of chlorodyne, by the simple method of placing a 1½*d.* Government stamp on the bottle. But we have every wish to place the sale of poisons under strict control and cordially agree with the authors of the Bill that companies should be brought within the provisions of the law.

THE MODE OF ACTION OF SUBCONJUNCTIVAL INJECTIONS.

AN interesting address on this subject has been recently delivered by Dr. Karl Wessely to the Natural History Society of Carlsbad. It has been fully reported in the *Deutsche Medicinische Wochenschrift* of Feb. 12th and 17th. Dr. Wessely's experiments were made upon rabbits and consisted in injecting beneath the conjunctiva solutions of various strength of sodium chloride and other salts and watching carefully their effects. The practice of subconjunctival injections has been employed and sometimes found useful in the infectious processes which occur after operations and wounds, in diseases of the cornea, in cases of acute and chronic iritis, in various forms of choroiditis, in detachment of the retina, in opacities of the vitreous, and in chronic degenerative processes such as retinitis pigmentosa. His experiments have satisfied Dr. Wessely that subconjunctival injections do not act through their osmotic power on the internal humours of the eye, since analyses have proved that their penetrating power is very small, that they do not produce their effect by acting as lymphagogues, nor, so far as regards sodium chloride injections, by any direct action in setting free leucocytes. They really act as powerful local stimuli to the conjunctiva which, even when frequently employed, have no injurious effects. The nerves of the conjunctiva thus energetically stimulated act in a reflex manner, presumably through the vaso-motor nerves on the vessels of the adjoining vascular territory, leading to the dilatation of the ciliary area. The hyperæmic condition of the ciliary vessels renders their walls more permeable and the result is the secretion of aqueous humour containing much albumin in place of the normal aqueous which contains none. Having determined these points experimentally Dr. Wessely proceeds to consider whether the effects of these injections are really serviceable and in what way they act and observes in the first place that we have long been accustomed to regard all the processes accompanying inflammation as constituting safeguards to the organism. Amongst others the œdema that accompanies inflammation has been so regarded without any precise reason being given for its efficacy. Bacteriological researches have, however, shown that the serum of normal blood contains several protective materials which play an important part in the strife against the lower organisms, and, moreover, that these materials, to which the names of bacteriolysin, agglutinin, hæmolysin, and precipitin have been applied, are in all probability associated with the albumin of the serum. The question immediately arose whether as the normal aqueous humour of the eye is almost destitute of albumin, whilst that secreted after subconjunctival injections contained a notable proportion of albumin, the beneficial effects observed might be due to the presence of ferments, enzymes, or solvents eliminated with it. Experiments made with animals rendered immune with the blood of the ox showed that the normal aqueous humour has no power of dissolving bovine blood corpuscles and hence contains no hæmolysin. But if a subconjunctival injection were made of a 5 to 10 per cent. solution of common salt, and after the lapse of half an hour the aqueous was withdrawn, it quickly dissolved an equal volume of a 5 per cent. mixture of blood corpuscles—a very interesting result—and still other experiments demonstrated clearly that the power of solution in the newly secreted aqueous was in direct proportion to the amount of albumin that the fluid contained.

THE MEDICAL REGISTER FOR 1903.

THE Medical Register for 1903 contains 1690 pages, as compared with 1647 last year. The foreign list, which was a new feature last year and then contained only one name, now contains five. On p. 76 of the Register is given a table showing the total number of medical men whose names are included in the Register on Dec. 31st in each year. On Dec 31st, 1902, there were 37,232 names. On Dec 31st, 1901, there were 36,912 names, and since then 1275 new names have been added, 96 restored, and 1051 removed, constituting a net gain of 320. The average number of names on the Register for the last five years is stated to be 36 279, so that the present number now exceeds that average by 953. Of the 1051 names removed, 700 were removed on evidence of death, 345 under Section XIV. of the Medical Act, and six under Sections XXVIII. and XXIX. of the Medical Act. Notwithstanding the fact that 700 names are stated to have been removed from the Register during the year on evidence of death—which is the highest number for 17 years—we have found, on comparing the Register for 1903 with the first 100 names in the obituary list at the end of the Medical Directory for 1903, that 12 of those names are still on the Register. As there are 607 names in the obituary list of the Medical Directory we hope that we may not assume that 72 names of deceased medical men are still on the Register for 1903. This is a very often-debated matter in these columns, but it does no harm to refer to it again, for the accuracy of the Medical Register is a matter in which the whole medical profession is profoundly interested. The name of a deceased member of the medical profession must be allowed to stand on the Register till complete evidence of his death is forthcoming; at the same time use might be made of the better information apparently at the disposal of the Medical Directory, and the deaths announced in that excellent book of reference might very well be inquired into by the registrar for purposes of verification. The presence on the Register of the names of dead persons is a real source of danger to the public. We notice that in two cases of medical men attached to the medical department of the King's household and of the Royal Family their titles are not included in the Register, although the titles of all the others are. We also observe that several errors have been made in the addresses. For instance, Edgbaston is called "Egbaston" and Sloane is called "Solane," and has been so printed for at least three years, and, further, the medical man in whose entry this slip occurs does not now live there. Cockfield is called "Cochfield," Pietermaritzburg is called "Pietermaritzberg," Rustenburg is described as in the "South African Republic," and Oulart is called "Outlart." But there is no need to multiply examples, which could probably be done, as our remarks are the result of only a few minutes' scanning of some of the pages. We are not making an attempt to find fault and we are quite aware of the immense amount of work that goes to the making of the official roll of the medical profession. Therefore we do not labour the points that we think might be urged against the compilation as a gazetteer or as a guide to the quick and the dead. There is no doubt that the Medical Register has become a vastly more accurate volume during the last two years than it was previously.

STREET NOISES.

EVERY year with the opening of the racing season the "winner" yeller wakes from his winter torpor and makes day and night hideous with howls like those of a banshee. The police, as represented by Sir Edward Bradford, and the London County Council, have both issued orders to deal with this nuisance, but they are fenced about with such absurd regulations that they are of no use. How can a busy man whenever he hears a "runner" be expected to leave his work, rush downstairs, keep one eye on the "runner," and look for a policeman with the other? But supposing that a constable is found simultaneously with the "runner" being near the only thing is that the latter's address is taken. He is then summoned and probably does not attend the summons. Even if he does more disturbance to work is caused by the annoyed citizen having to attend the court and most probably the "runner" is fined 6*d*. or some entirely inadequate sum. What is wanted is for the police to have power forthwith to arrest any newsmonger who shouts. The London County Council has just increased its rate. It is only fair that it should do something to urge upon the Home Office that the police should be enabled to control a nuisance which has become perfectly unbearable. The nuisance is most acute on the day of a big race and if only the police authorities would on the day of, say, the "City and Suburban" station a plain-clothes man at the bottom of Bedford-street, Strand, with directions to take a note of the number of "runners" who yell perhaps even the official mind would be stirred to desert its attitude of Gallian indifference.

THE NEW PAPYRUS OF TIMOTHEOS OF MILETUS' POEM ON THE PERSIAN WAR.

CERTAINLY up to the present time *few* more precious relics of ancient literature have been found preserved for us by the perfection with which the Egyptians carried out their burial rites than the magnificent poem of Timotheos of Miletus contained in a papyrus found last year in a sarcophagus beside a body at Abusir. Such a subject may perhaps be deemed extraneous to the contents of a medical journal, but that is hardly so in such a special case as this. Any really elevated and exquisite production of the poetic fancy such as this is calculated to be a mental consolation and thus a physical assistance to many a jaded, overworked citizen subject to the tension of modern life as well as to the actual invalid. *To the medical* man who turns from his weary round for some change of thought a masterpiece such as this, if he still retains his scholarship, will be a literary pleasure and for the benefit of those who have forgotten their Greek it may be expected that a translation will soon be forthcoming. It would be singular, if it is true as has been alleged that the poetic genius of the race shows sinister signs of diminution in recent years, that the balance should be redressed by the recovery of masterworks of the classic muse. Within something like a decade the lost poems of Herondas, Bacchylides, and now the great ode of Timotheos have been restored to us and it is not too much to anticipate that these are but precursors of a greater harvest.

THE PRODUCTION OF ARSENICAL GASES BY LOW ORGANISMS.

IT is curious and not a little startling that the fungus concerned in forming the green mould on cheese or on jams is an arsenic eater, and there can be little doubt that this power of certain low organisms of assimilating arsenic has in some cases accounted for the poisonous symptoms ensuing upon sleeping in rooms furnished with arsenical wall-papers. It has been shown that many of the moulds when placed in suitable nutrient fluids containing arsenic will gradually assimilate the arsenic, ultimately expelling it in the form of arsenical gas. In this way a comparatively inert arsenical compound may be converted into a powerfully poisonous gas. The action of the fungus may easily be demonstrated. For example, if a raw potato be taken and a very weak arsenical fluid be brushed on its freshly cut surface and inoculated with one of the arsenic-assimilating moulds, such as the common penicillium glaucum or the mucor mucedo, a persistent odour will sooner or later be developed unmistakeably like garlic which is due to the evolution of arsenical gas. A sop of bread may be substituted for the potato and is said to give even more marked results. So readily do these fungi select the arsenic that they have been employed, so to speak, as detectives of the poisonous metal when present in quite minute quantities. In fact, these low organisms have been employed in toxicological investigations, the test, it is stated, being more delicate than chemical methods. In the same way the presence of arsenic may be detected in wall-papers, in dye-stuffs, or other fabrics which may be examined directly without the preliminary trouble of destroying the organic matter, which is often necessary in chemical methods.

THE HEALTH OF WAGNER.

IN a leading article which appeared in THE LANCET of March 7th, p. 672, we discussed the theory put forward by Dr. G. M. Gould of Philadelphia as to the relation between dyspepsia and eye strain. Dr. Gould took as instances the following five well-known workers, all of whom suffered from dyspepsia—De Quincey, Carlyle, Darwin, Huxley, and Browning—and maintained that they all suffered from some error of refraction. Mr. W. Ashton Ellis, M.R.C.S., is now issuing an English version of Herr Glasenapp's "Life of Richard Wagner," although he has added to the original German some interesting details founded upon lately discovered Wagner records. In Vol. III., a book of some 500 pages representing but 100 of Herr Glasenapp's work, we find many allusions to Wagner's state of health. He seems to have suffered much from dyspepsia, together with all the troubles attendant on the toxæmia set up by that condition, and in particular we note that while he was writing the *Niebelungen Ring* he complains of constant headache. Mr. Ashton Ellis considers that this headache was due to migraine, and certainly the symptoms of which Wagner complained were very much those of migraine, although he talked about the pain being "like a sharp knife cutting into the nerves of my brain." In the experience of most people, however, the migraine pain is more like a blunt nail being driven into the head. Errors of refraction are a well-known cause of migraine and it is quite possible that Wagner suffered from such errors. Migraine, however, is common in highly wrought persons of the artistic temperament, and Wagner lived his life to the full and was moreover by no means a normal person. Poet, dramatist, revolutionist, a musician without compeer in his own particular line, one with a mastery of the orchestra comparable to that of Swinburne over words and rhythms or of a mediæval architect over stones and the intricacies of tracery and groining, what wonder that the mere physical body sometimes gave way under the nervous strain with which Wagner's art treasures were produced.

A STRANGE METHOD OF COMMITTING SUICIDE.

IN a leading article which appeared in THE LANCET of Oct. 5th, 1901, p. 921, entitled "Peculiar Methods of Suicide," we mentioned the case of a man who killed himself by means of an ingeniously constructed guillotine. A similar case has recently been reported from Rheims. A man procured a spade, sharpened the edge, and fixed the implement, blade downwards, to the end of a carpenter's bench which he weighted heavily. He then placed a block of wood under the same end of the bench in such a fashion that the block could easily be removed and so let the bench fall together with the sharpened blade. When these preparations were completed the man lay down and placed his neck on a thick piece of wood directly under the spade and knocked the supporting beam away with the result that he was immediately decapitated.

ON ASPIRIN AS AN ANALGESIC IN CARCINOMA.

IN the *Allgemeine Wiener Medizinische Zeitung* of March 17th Dr. Gustav Breuss of Vienna strongly recommends the use of aspirin for the relief of pain in inoperable carcinoma. Numerous observations have been made on the analgesic effect of aspirin in neuralgias and other painful affections, but only very few on its use in carcinoma. Dr. Witthauer[1] gave doses of one gramme of aspirin once or twice daily in three cases of inoperable carcinoma with beneficial results. Dr. Merkel obtained good results in a case of severe rectal carcinoma by the administration of four grains in small doses, and several other observers agree as to its usefulness in uterine carcinoma. Dr. Breuss has made a trial of it in several cases, chiefly of this last disease, and has been in all cases gratified by the result. He uses one-gramme powders and administers two or three daily. He believes that it postpones the ultimate use of morphia injections very considerably and even when these are unavoidable renders a smaller quantity effective.

THE DANGERS ATTACHING TO THE PERSISTENCE OF MECKEL'S DIVERTICULUM.

THE diverticulum of Meckel, the persistent vitelline or omphalo-mesenteric duct, is found in no small proportion of cases, but fortunately it is only rarely that harm results from its presence, for at many a necropsy it is discovered when the history makes it clear that it has never given rise to any symptoms. In two or three ways this "vestige," however, is dangerous. When the diverticulum is unattached by its extremity it has but little tendency to produce any morbid effects, but if it is attached by the tip it may readily lead to acute intestinal obstruction by pressing on and constricting a coil of bowel. Many cases of this occurrence have been recorded and a large proportion end in recovery if an early laparotomy is performed for relief of the obstruction, for the patient is generally a youth or a young adult and stands the operation well. There is, however, another mode by which the diverticulum may cause symptoms. Should the finger-like process become inverted into the cavity of the ileum, it will in all probability act like a foreign body and will give rise to peristalsis, and the persistence of this peristalsis will lead to an invagination of the portion of bowel to which the abnormal process is attached, and thus an intussusception will be developed. The museum of the Royal College of Surgeons of England contains a specimen showing an inverted Meckel's diverticulum which led to a fatal intussusception. An instance of this rare cause of intestinal invagination is recorded in this number of THE LANCET and the successful issue was due to the early recognition of the intussusception by the medical man, Mr. E. L. Hunt of Shenstone, and the prompt operative treatment which was was adopted by Mr. H. G. Terry at the Bath Royal United Hospital. Mr. Carwardine has reported a case in which a still rarer morbid condition resulted from the presence of a persistent vitelline duct. A child died when three days old and it was found that a large Meckel's diverticulum existed and that this had become distended with meconium and had taken a twist of three turns, when complete intestinal obstruction had occurred.

---

[1] Therapeutische Monatshefte, October, 1900.

A DISCUSSION will take place at the Hunterian Society upon the Present Methods of treating Tuberculosis on the evenings of Wednesdays, April 8th and 22nd, commencing at 8 30. On Wednesday, April 8th, an introduction to the discussion will be made by the President, Dr. Stephen H. Appleford. A debate on the Treatment of Tuberculosis in Sanatoriums compared to that in Private Practice will be opened by Dr. G. Newton Pitt; Dr. H. G. Felkin will open a debate on the Influence of Location; and Dr. T. N. Kelynack will open a debate on the Selection and Classification of Patients in Sanatoriums. On Wednesday, April 22nd, Dr. T. H. A. Chaplin will open a debate on Infection, Reinfection, and Multiple Infection; the Surgical Aspect of the Treatment of Tuberculosis will be discussed by Mr. W. Knight Treves; and Modifications with respect to Comfort, Exercise, Rest, and Recreation will be suggested for consideration by Dr. T. Glover Lyon. There will be an exhibition of plans and models of sanatoriums in the theatre of the London Institute, Finsbury-circus, E C., where the discussion will be held and where a lantern and screen will be available for the exhibition of slides.

THE reports by the chemist and the medical officer of health, together with a bacteriological report by Dr. F. W. Andrewes, on the condition of the atmosphere of the Central London Railway, have been printed for the London County Council and published this week. The conclusions are identical with those upon which we commented in our issue of Feb. 21st, p. 538. While the amount of carbonic acid gas considerably exceeds that found in the air above the ground the number and kind of organisms were practically the same as those in the outside air. There is no reference to the existence, origin, or nature of the peculiar sickly smell of the air in the tube.

Dr. J. McNaughtan, medical officer of the Scotch *Prison* Service, and Mr. N. A. Humphreys, the chief clerk to the Registrar-General's Department, have been appointed by the King as Companions of the Imperial Service Order in recognition of long and meritorious service in the Civil Service.

HIS MAJESTY THE KING has acceded to the request of the board of management of the National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen-square, Bloomsbury, to accord his patronage to the charity.

Professor W. A. Tilden D Sc., F.R.S., has been elected President of the Chemical Society.

THE ROYAL NAVY MEDICAL SERVICE.

THE First Lord of the Admiralty, Lord Selborne, distributed the prizes on March 31st, at Haslar Hospital, to the successful candidates in the instructional course at the Royal Navy Medical School. The ceremony took place in the library attached to the museum and the company numbered about 70, chiefly composed of the student surgeons and of the medical officers from the various establishments in Portsmouth harbour, from the harbour ships, and from the Marine depôts.

Sir H. F. NORBURY, Director-General of the Medical Department of the Royal Navy, said that they were all glad to welcome Lord Selborne at Haslar Hospital and proceeded to read the report of the inspector-general on the work and conduct of the students who had attended the course of instruction at the school. He was glad to say that the sum total of the marks gained compared favourably with the totals recorded on former occasions.

Lord SELBORNE then presented the gold medal and a microscope to Surgeon M. J. Laffan, and the silver medal and some books to Surgeon A. D. Spalding.

Lord SELBORNE then proceeded to address those present and said: It has been the greatest pleasure to me to come here to-day to give away the prizes at the end of this course The Haslar Naval Hospital is the headquarters of the medical department of the navy, and I always think that one of the great glories of the naval service is that it takes to itself all the other great professions—the priest, the soldier, the engineer, and the surgeon—and gives to each of them a blend of the sea in addition to his own peculiar professional qualities, and in every sense he is the better for this blend of the sea. Sometimes I am told that although a man may be the better for it he is handicapped in his professional career by the absence of certain opportunities. Now, to take the case of the medical officer, I quite admit that in the navy you will not have *all those opportunities for constant observation and* varied practice which your friends, the civil practitioners, may have. I also admit that in going into the navy you are abandoning the chance of those great prizes and of the wealth which the more fortunate medical man in civil practice may acquire But remember that it is not always the man who deserves success who obtains it and there is many a clever medical man in civil practice who has never yet achieved that wealth which his real ability with opportunity should have enabled him to attain. There are many qualities that make for success, which is achieved not by ability alone but by a combination of many qualities and also by luck. In deliberately exchanging this chance by entering the naval service you know that you have achieved for yourself a perfect certainty of position. You have looked forward into the future of your life and know exactly what your life can be. You can say to yourself, "If I choose I can serve my country with great honour to myself and advantage to the service" You leave care in its strictest sense behind you and you know what the future will give you If you have the merit you can achieve great honour for yourself and your family. Perhaps the Admiralty has not done all that it might have done in the past towards enabling the naval medical man to keep pace with the scientific progress and advance of medicine, but there has been great difficulty in the matter owing to the shortage of medical officers. The navy has expanded by leaps and bounds. Nearly 130,000 men will be voted for the navy next year, whereas they had only 60 000 15 years ago. It has been difficult for the medical department of the navy to keep pace with this great expansion, and it has followed that there has not been the number of officers to make it possible for the Admiralty to give the study leave between commissions which I admit frankly is essential if an officer is to keep abreast with the scientific advances in his profession. But it is very little after all that the Admiralty can do for them because a man is really what he makes himself and not what the Admiralty makes him or any other body of people can make him. What you have to ask yourselves all through your professional life is this: "I know the disadvantages which I suffer from in comparison with my civilian friends, but am I using all the advantages I have?" How many of your civilian friends will have the opportunities of study that you will have? If you choose you can use the time at your disposal to keep yourself abreast of advances in medicine by reading the literature of your profession. Again, you will have very peculiar opportunities of observation which are denied to your civilian friends at home. Your special service will give you special opportunities. I sometimes wish very much that the great triumphs of Manson and of Bruce had been naval triumphs and whether they were to have a naval conquest of that sort was as open to the naval officer as it was open to Dr. Manson. We are only at the beginning of our knowledge in these matters and although you will not have those opportunities of constant study into the mystery of cancer which your friends at home will have yet there is the almost equal mystery of Mediterranean fever which the civilian at home will not have the opportunity of studying and which is a world of science for you to conquer. You know what work has been done at Haslar and at Malta—and I may say that at those places perhaps more has been learned in respect of the true knowledge of Mediterranean fever than in any other laboratories in the world; still the opportunities that you have of studying this subject are very great and you know much better than I do how much greater they are. Apart, however, from these special opportunities of study I want each of you officers entering the naval medical service to remember that it is your duty by every suggestion that you can make to contribute to the welfare of the service and the advancement of medical science. Do not think that suggestions are not welcome. In my opinion, the man who shuts his ears to suggestions is a fool; the man who is successful in his work, who gets the reputation of always being able to overcome the difficulties of the moment, who has a reputation for resourcefulness, is in nine cases out of ten a man who opens his ears to any suggestions that others may bring him. I could not do my work as First Lord of the Admiralty for one week on my own brain. It is because I am only too glad—and my colleagues are only too glad—to have suggestions in regard to the solution of problems that the work is carried on. We never shut our ears to any suggestions whatsoever. Many suggestions doubtless are futile and also foolish, but if you are not prepared to listen to them you will not get the advantage of any good suggestion that may be offered. What I say is that it is the duty of everyone in responsible positions of authority to receive suggestions and it should be the ambition of all young officers to make suggestions, of course only after careful thought and accurate observation. If an officer makes random suggestions he is destroying, and deservedly so, his own reputation. The study of these questions applies to every department of the work that lies before you. Take the battleship, for instance, in which you will serve. There is a problem, as yet unsolved, that has puzzled the brains of the most capable and experienced officers—the problem of forecasting the conditions under which it will be possible to deal with the wounded in naval actions. No one quite knows, because the conditions will be so different from any of which they have had any experience. I was told only a day or two ago that Sir Frederick Treves had said about the war in South Africa that if a tent could be pitched over every wounded man where he fell and if he could be treated there the loss of life in war would be enormously diminished. The loss of life is from the moving of the wounded man and not so much from the wound received. In a battleship you have practically a tent over the man where he falls, but all the men could not be treated immediately. There would not, however, be all that difficulty in dragging him to a base hospital in a cart or heavy wagon causing him to be torn asunder with pain. The difficulty, however, remains of how the medical officer is to get at the wounded. I only put this forward as a kind of idea that occurred to me of the sort of problem I would try to solve if I were a naval medical officer. The King, the country, and the Board of Admiralty mean the navy to be the best navy in the world. That does not mean only the best ships and the greatest number of them but that every part of the navy shall be perfect in every part of its administration. Consequently the naval medical department must be perfect and that depends in the first place on the officers and then on the appliances which on their advice the Admiralty supplies. I consider it to be the duty of the Board of Admiralty to spare no money which the taxpayer will give to put everything at your disposal that science can suggest to make the naval medical service a pattern to all the medical services in the world. In conclusion I congratulate you, Staff-Surgeon Bassett-Smith, on the success of this course for which you are chiefly responsible, and I also congratulate you on your promotion which I now inform you that the Board of Admiralty has conferred upon you.

Sir HENRY NORBURY then proceeded to read the marks obtained by the student surgeons attending the instructional course.

Inspector-General R. W. COPPINGER, in charge of Haslar Hospital, then expressed the thanks of those present to Lord Selborne for his presence at the gathering.

Lord SELBORNE briefly replied, saying that he was much indebted to them for the kind invitation to be present.

The proceedings then terminated.

THE THIRD REPORT OF THE ROYAL COMMISSION ON SEWAGE DISPOSAL.

As shown in its third report just issued the labours of the Royal Commission on Sewage Disposal cannot be considered to be near the end. In fact it is obvious that the Commissioners find that the scope of their inquiry widens as their investigations are pursued. The contamination of oyster beds is a case in point. It is equally obvious that they are gathering information of the most valuable kind and that the members are a very capable body of men who mean to make their inquiry as thorough as possible. It will be remembered that the Commission was appointed in 1898 "to inquire and to report what methods of treating and disposing of sewage may properly be adopted." Three years after this appointment was made an interim report was issued which was dealt with in a leading article in THE LANCET of August 10th, 1901, p. 376. In this report the Commissioners felt justified in concluding (1) that peat and stiff clay land are generally unsuitable for the purification of sewage; (2) that it is practicable to produce by artificial processes alone, either from sewage or from certain mixtures of sewage and trade refuse, effluents which will not putrefy (this conclusion led to the Commission expressing the opinion that under proper safeguards the present rule as regards the application of sewage to land might be modified); and (3) that the creation of a separate commission was demanded or a new department of the Local Government Board which shall be a supreme rivers authority dealing with matters relating to rivers and their purification. In the second report the methods of bacteriological analysis adopted by the Commission were described and at the same time the importance of bacteriological examination was emphasised in view of the fact that though purification of sewage was undoubtedly effected by bacterial agencies, yet the resulting effluents were not bacteriologically satisfactory owing to the presence in them of large numbers of organisms of the colon series.

The third report deals with some very important aspects of the inquiry. In the main it relates to the question of the disposal and treatment of trade effluents. It is well known that sewage containing trade effluents is generally more difficult to purify than is ordinary sewage. The Commission finds that these difficulties arise from the fact that trade effluents may be turned into the sewer at irregular intervals and that they may contain large quantities of solid matters in suspension which tend to choke the purification plant and that they may be very acid or very alkaline or otherwise chemically injurious. In spite of these facts, however, the results of practical inquiry "fully support the view that it is practicable in the great majority of cases to purify mixtures of sewage and trade effluents if the manufacturers adopt reasonable preliminary measures." The conclusion follows that the law should be altered so as to make it the duty of the local authority to provide such sewers as are necessary to carry trade effluents as well as domestic sewage and that the manufacturer should be given the right, subject to the observance of certain safeguards, to discharge trade effluents into the sewers of the local authority if he wishes to do so. There are cases, however, in which the local authority should obviously be relieved of this duty—as, for example, when the effluent discharged from the manufactory is of a composite character, the greater part of which might with advantage be easily dealt with by the manufacturer if it were keep separate. It is undoubtedly difficult to generalise upon this matter and therefore it is suggested that in individual or special cases the only solution of the problem would be the appointment of some tribunal which would be empowered to settle any differences arising between the local authority and the manufacturer. There is no doubt that money now wasted over prolonged litigation would be more than sufficient to pay the expenses of a [illegible] such a tribunal would be [illegible] machinery for the settle[illegible] authorities and manufacturers is not only unsatisfactory but costly. The law courts have over and over again been shown to be unsuitable for the determination of these questions. [illegible] recommendation [illegible] central authority [illegible]fferences between [illegible]. It is proposed [illegible]d possess its own laboratory [illegible] officers (1) an administrative [illegible]ng special knowledge of the bacteriology of sewage, trade effluents, and water-supply; (3) a chemist having special knowledge of the chemistry of the same; and (4) an engineer having a special knowledge of geology and water-supply. It is also proposed that an epidemiologist should be added to the staff of the central authority in connexion with the pollution of rivers and the protection of sources of water-supply. In fact, besides the question of settling disputes as to the discharge of waste and sewage into sewers and rivers the central authority, it is suggested, should exercise a general superintendence over the whole country in regard to the prevention of the pollution of water.

The Commissioners are continuing their investigations in regard to a number of artificial processes of dealing with the disposal of sewage. They are also investigating the question of the discharge of sewage, sewage effluents, and [illegible]aters with especial [illegible]sh. Again, investi[illegible]pose of ascertaining [illegible] possibly dangerous micro-organisms which are common in sewage effluents in those instances in which they are discharged into a river from which water for drinking is drawn. Finally, the methods available for the satisfactory disposal of industrial effluents when not mixed with ordinary sewage are shortly to receive consideration. We doubt whether a Royal Commission has ever before faced a more intricate subject or one developing more paths of investigation than that which is [illegible]te in all [illegible]ms. Its [illegible] original research.

MEDICINE AND THE LAW.

An Employment of Children Bill.

A BILL of some importance has been introduced in the House of Commons with a view to making better provision for regulating the employment of children, where it has not been already regulated by Act of Parliament. This is a Government measure introduced by the Home Secretary. It is proposed that the objects of the Bill should be mainly carried out by county and borough councils, to which large [illegible]-laws within their juris[illegible]ons or to any specified [illegible]low which children are [illegible] hours of employment. These by-laws may also prohibit absolutely or permit subject to conditions the employment of children in any specified occupation which may be shown to be dangerous to health or to morals. It is further forbidden by the Bill itself, as distinct from the by-laws to be made by local councils, that children should be employed at night or when under 11 years of age for the purposes of street trading, or for lifting heavy weights likely to injure them, or, generally, in any occupation likely to be injurious to the life, limb, or health of the child, regard being had to his physical condition. County and borough councils are empowered to make by-laws to regulate street trading by persons under 16 years of age, but for the general purposes of the Bill, and subject to specified exceptions, a child is defined as one under 14 years of age. Provision is made for the submission of by-laws to the Secretary of State and for enforcing by suitable penalties the Bill and by-laws made under it. Fines are provided for those who employ children in contravention of this Bill, for parents and guardians who knowingly permit such employment, and in the case of persons under 16 years of age trading in contravention of by-laws the offender may be fined or, if under 14 years of age, may for repeated offences be sent to a reformatory. From the brief outline thus given it will be seen that this Bill, though possibly open to criticism and amendment, is one which merits serious attention from all those to whom the morals and health of the young are matters of interest and solicitude.

Another Vaccination Bill.

Besides the Bill introduced by Mr. Channing to provide that no prosecution under the Vaccinaton Acts shall be held without the authority of the guardians, another—inspired by similar sympathies and prejudices—would enact that: "From and after the passing of this Act no parent or person having the custody of a child shall be compelled or ordered to vaccinate such child by any justice, court, or other person, having authority hitherto, to so compel or order; and so much of Sections 29 and 31 of the Vaccination Act of 1867 as enacts that any parent or person having the custody of a child shall be compelled or ordered as aforesaid is hereby repealed." For this legislative effort Mr. Broadhurst is responsible. It is backed by Mr. Thomas Bayley, Sir John Rolleston, Mr. Channing, and Mr. Corrie Grant.

Grocers' Licences.

A large number of the private Bills introduced in the House of Commons relate to matters indirectly of interest to the medical profession, such as those which refer to the housing of the working-classes and to the drink question. Of those which deal with the latter topic two have for their object the freeing of tied houses and one aims at doing away with what are known as grocers' licences in Scotland. The dangers which have arisen, particularly with regard to women, through the sale of wines and spirits by grocers and provision dealers are too well known to require recapitulation. The Bill in question recites in its preamble that "the combination of the grocery and spirit trade in Scotland has been productive of great evil," and proposes to forbid the granting of licences to grocers and provision dealers and the carrying on of grocery and provision businesses by licensed persons after specified dates in the year 1905. The Bill is brought in by Sir John Leng and is backed by Mr. Crombie, Mr. Dalziel, Mr. Pirie, and Mr. Hunter Craig.

A Criminal of Doubtful Responsibility.

Dr H. Crutchley of Alsager has written a letter to the *Staffordshire Sentinel* calling attention to the conviction of a man named Bagnall upon his own confession at the Staffordshire assizes for a serious assault. The prisoner was apparently employed at a pottery and it was the duty of the person assaulted (Mr. Gater) to superintend his work. Mr. Gater found fault with some jug handles and having turned away was violently attacked by the prisoner who threw jugs and moulds at him and also drew a knife. He then had a "seizure" or "fit" and when he became conscious again denied all knowledge of what he had done. Dr. Crutchley refers to the article, "Insanity and Epilepsy," p. 342, vol. viii. of Allbutt's System of Medicine, 1899, and [illegible] between the successive acts of [illegible] there detailed as preceding and [illegible]ommitted by epileptic patients. Dr. Crutchley makes out a strong case in favour of his view that Bagnall "was sentenced for an uncontrollable act committed when reason was dethroned," and expresses the hope that steps will be taken to obtain an alteration of the sentence of two months' imprisonment by questions in the House of Commons or by direct application to the Home Secretary. A difficulty would presumably arise in this case owing to Bagnall having, as Dr. Crutchley says, "been advised to plead guilty," which presumably means that, whatever his position may have been, he had the advantage of legal assistance and formally admitted his crime. We should be inclined to think, however, that the Home Office would give serious consideration to a communication with reference to a recently sentenced prisoner, supported by the opinion of a medical man having knowledge of the facts of his crime and trial, even in circumstance such as those described. Reference to the latest criminal statistics shows that in the year 1901 out of 791 criminal lunatics under detention 113 had been certified after conviction, and that on the Home Secretary's advice the prerogative of mercy was exercised by the Crown in 420 instances for various reasons. These figures would seem to show that the case of the condemned prisoner is not hopeless even after sentence has been passed upon him. It must be remembered, from another point of view, that if the prisoner serves his term of imprisonment the matter will be closed. This may be more satisfactory to him than the other courses which might have been adopted had the evidence been gone into.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8820 births and 4682 deaths were registered during the week ending March 28th. The annual rate of mortality in these towns, which had been 16·6, 17·2, and 17·0 per 1000 in the three preceding weeks, further declined to 16·2 per 1000 last week. In London the death-rate was 16·5 per 1000, while it averaged 16·1 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·3 in Handsworth, 6·7 in Hornsey, 8·7 in Grimsby, 8·8 in Walthamstow, 9 4 in Willesden, 9·8 in Wallasey, 10·6 in King's Norton, and 10·9 in West Hartlepool; the highest rates were 20·6 in Hanley and in Bootle, 20·8 in South Shields, 21·5 in Bury, 21·9 in Manchester and in Rotherham, 22·4 in Swansea, and 26·1 in Stockton-on-Tees. The 4682 deaths in these towns last week included 489 which were referred to the principal infectious diseases, against 501, 483, and 492 in the three preceding weeks; of these 489 deaths 157 resulted from measles, 121 from whooping-cough, 68 from diphtheria, 60 from diarrhœa, 35 from scarlet fever, 35 from "fever" (principally enteric), and 13 from small-pox. No death from any of these diseases was registered last week in Hastings, Brighton, Ipswich, Smethwick, or Grimsby; among the other towns they caused the lowest death-rates in Willesden, Plymouth, Preston, Halifax, and Leeds, and the highest rates in Croydon. Tottenham, West Bromwich, King's Norton, Wigan, Bury, Salford, Rotherham, Rhondda, and Swansea. The greatest proportional mortality from measles occurred in Croydon, Tottenham, West Ham, Devonport, West Bromwich, Kings Norton, Wigan, Salford, Tynemouth, and Swansea; from scarlet fever in St. Helens; from diphtheria in Hanley and Swansea; from whooping-cough in Croydon, Tottenham, West Bromwich, Leicester, Stockport, Wigan, Manchester, Oldham, and Rotherham; and from "fever" in Rhondda. Seven fatal cases of small-pox were registered in Liverpool, and one each in Walsall, Birkenhead, Bury, Manchester, Rochdale, and Blackburn, but not one in any other of the large towns. The number of small-pox cases under treatment in the Metropolitan Asylums hospitals, which had been six, seven, and seven at the end of the three preceding weeks, had further risen to 11 at the end of last week; five new cases were admitted during the week, against two in each of the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of the week was 1756, against 1790, 1798, and 1789 at the end of the three preceding weeks; 213 new cases were admitted during the week, against 193, 231, and 220 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 251, 258, and 282 in the three preceding weeks, declined again last week to 250 and were 203 below the corrected average number. The causes of 48, or 1·0 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Leicester, Nottingham, Salford, Newcastle-on-Tyne, and in 48 other smaller towns; the largest proportions of uncertified deaths were registered in Hanley, Birmingham, Liverpool, Sheffield, Rotherham, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·5, 19·7, and 20·1 per 1000 in the three preceding weeks, declined again to 18·6 per 1000 during the week ending March 28th, but showed an excess of 2·4 per 1000 over the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 15·0 in Leith and 15·1 in Paisley to 19·8 in Glasgow and 21·7 in Dundee and in Perth. The 609 deaths in these towns included 37 which were referred to whooping-cough, 17 to diarrhœa, 12 to measles, five to "fever," three to scarlet fever, and three to diphtheria, but not one to small-pox. In all 77 deaths resulted from these principal infectious diseases last week, against 75, 67, and 68 in the three preceding weeks. These 77 deaths were equal to an annual rate of 2·4 per 1000, which was 0·7 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 32, 28, and 32 in the three preceding weeks, further rose last week to 37, of which 22 occurred in Glasgow, six in Edinburgh, five in Greenock, and two in Dundee. The deaths from diarrhœa, which had been 12 and 14 in the two preceding weeks, further rose to 17 last week, and included nine in Glasgow, four in Dundee, and two in Aberdeen. The fatal cases of measles, which had been 15 and eight in the two preceding weeks, increased again last week to 12, of which five were registered in Aberdeen, four in Edinburgh, and two in Glasgow. The deaths referred to different forms of "fever," which had been two, three, and five in the three preceding weeks, were again five last week and included three in Glasgow and two in Edinburgh. The fatal cases of scarlet fever, which had been four and six in the two preceding weeks, declined again last week to three and were all registered in Glasgow, where the three deaths from diphtheria also occurred. The deaths referred to diseases of the respiratory organs in these towns, which had been 97, 117, and 134 in the three preceding weeks, declined again last week to 100, and were 73 below the number in the corresponding period of last year. The causes of 16, or nearly 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 27·8, 26·6, and 27·7 per 1000 in the three preceding weeks, further rose to 29·3 per 1000 during the week ending March 28th. During the past four weeks the death-rate has averaged 27·9 per 1000, the rates during the same period being 16·6 in London and 19·7 in Edinburgh. The 213 deaths of persons belonging to Dublin registered during the week under notice showed an excess of 12 over the number in the preceding week and included 18 which were referred to the principal infectious diseases, against nine, 10, and eight in the three preceding weeks; of these, six resulted from whooping-cough, three from "fever," two from measles, two from scarlet fever, two from diphtheria. two from diarrhœa, and one from small-pox. These 18 deaths were equal to an annual rate of 2·5 per 1000. the death-rate last week from the same diseases being 2·1 per 1000 both in London and in Edinburgh. The fatal cases of whooping-cough, which had been two in each of the two preceding weeks, increased last week to six. The deaths from "fever," which had been two in each of the two preceding weeks, rose to three last week. The fatal cases of diphtheria, which had been two and three in the two preceding weeks, declined again to two last week. The deaths from diarrhœa numbered two last week, against one in each of the two preceding weeks. The 213 deaths in Dublin last week included 35 of children under one year of age and 59 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a slight decline from the respective numbers recorded in the preceding week. Four inquest cases and seven deaths from violence were registered. and 83, or nearly two-fifths, of the deaths occurred in public institutions. The causes of 11, or more than 5 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon W. E. Bennett to the *Clyde*. Staff Surgeons P. W. Bassett-Smith and G. Welch to be Fleet Surgeons, with seniority of March 26th, promoted for conspicuous merit; J. H. Whelan to the *Edgar*, on commission, to date April 9th. Surgeons: E. A. Shaw, F. H. A. Clayton, F. J. A. Dalton, and E.

Sutton to be Staff Surgeons, with seniority of March 26th, promoted for conspicuous professional merit; R. W. B. Hall to the *Edgar* on commission.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Rowney is placed under orders for service in India. Major E. C. Freeman has arrived at Portsmouth for duty. Colonel Rooney is placed on retired pay. Dated March 22nd, 1903. Lieutenant-Colonel Rennie retires on retired pay. Dated March 28th, 1903.

The transfer to temporary half-pay on account of ill-health of Major J. I. P. Doyle will take effect from Dec 1st, 1902.

The confirmation of the undermentioned Lieutenants in that rank, which was notified in the *London Gazette* of March 10th, 1903, is cancelled: W. F. Ellis and F. L. Henderson.

IMPERIAL YEOMANRY.

Suffolk (The Duke of York's Own Loyal Suffolk Hussars): Walter John Hervey to be Second Lieutenant. Dated March 28th, 1903. Surrey (the Princess of Wales's): Reginald Courtenay Gayer to be Surgeon-Lieutenant. Dated March 17th, 1903.

ROYAL ARMY MEDICAL CORPS (MILITIA).

Lieutenant-Colonel Sir J. R. A. Clark, Bart., C.B., is granted the honorary rank of Colonel. Dated March 5th, 1903.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 2nd Glamorganshire: Lieutenant S. H. Hoyle to be Captain (dated March 28th, 1903); Surgeon-Lieutenant C. C. Parsons to be Surgeon-Captain (dated March 28th, 1903).

Rifle: 2nd Volunteer Battalion the York and Lancaster Regiment: Alfred Robinson to be Surgeon-Lieutenant. Dated March 28th, 1903.

THE KING'S BIRTHDAY.

Notice is given in the *London Gazette* that the King's Birthday will be celebrated in London and at all home stations on Friday, June 26th. At all foreign stations His Majesty's Birthday will be celebrated on Monday, Nov. 9th.

WAR OFFICE REGULATIONS ABOUT THE CHARACTER OF ARMY RECRUITS.

A War Office circular memorandum has been issued with the view of preventing the enlistment of undesirable characters into the regular army and militia. No man is to be accepted in future in any branch of these services who cannot produce a satisfactory reference as to his character and antecedents. If this is not forthcoming, steps are to be taken to obtain the man's character. The recruiting officer is to satisfy himself that the candidate is in every respect a suitable man for enlistment. In order that desirable men may not be lost to the army whilst inquiry is being made recruits may be attested but will not be finally approved until a satisfactory character is forthcoming.

Correspondence.

"Audi alteram partem."

THE RETARDED PULSE WAVE IN AORTIC REGURGITATION.

To the Editors of THE LANCET.

SIRS,—Dr. Paul M. Chapman in THE LANCET of March 28th, p. 869, quotes me as having said that "the pulse in aortic regurgitation is always retarded or delayed." I beg permission to complete the sentence—"that is, there is an appreciable interval between the beat of the heart, the carotid pulse, and the pulse in the radial artery, which varies according to the extent of the incompetence." The observation was not considered sufficiently important from a clinical point of view to demand full discussion, since the increased interval between the apex beat, the carotid throb, and the radial pulse is simply an incident of the condition of the arterial circulation which gives rise to the collapsing pulse, and while on this account it is interesting the pulse is more trustworthy as evidence of the degree of incompetence.

In examining the question of pulse delay, whether by clinical observation or by experiment, the first point to be made clear is that the case is one in which the regurgitation is considerable. There may be a loud diastolic murmur when the amount of blood re-entering the ventricle is inconsiderable, more particularly when the incompetence is a sequel of degeneration of the aorta with dilatation and rigidity of its walls. Here the absence of delay in the carotid and radial pulse is an item of evidence of the slight [illegible] ticity in the aorta. Or, [illegible] with the incompetence [illegible] pressure which gives rise [illegible] the retardation need not occur.

Since Dr. Chapman's patient was a young man the first of the conditions cannot be present, but a scientific question being at issue it would have been better to have given the evidence on which was based the statement that there was [illegible] idial [illegible] and [illegible] the murmur or murmurs, and the presence or absence of the aortic second sound. Even the pulse trace, which in aortic incompetence usually has great significance, in Fig. 2, so far as I can make it out, tells us nothing whatever as to the amount of regurgitation, and I should be disposed to interpret the cardiogram as indicating stenosis as well as incompetence. I should further infer the existence of stenosis from the statement that the heart muscle was largely hypertrophied, and especially from the fact that the duration of the systole was at its extreme maximum.

I try to keep my eyes open and my mind free from prepossession, but I have found no reason to doubt the accuracy of the observation that in real aortic incompetence there is delay in the carotid throb and radial pulse. Let anyone sit down before a case in which the physical signs of regurgitation enumerated above are well marked, with the tip of the finger of one hand on the apex beat, his eye on the carotid, and the fingers of the other hand on the radial pulse with the hand well raised, and, according to my experience, he will be able to count one, two, three, as one event follows the other. I have, indeed, found in aortic regurgitation with a failing heart and demonstrated to a class of students an intermission of the apex beat synchronous with the beat of the pulse belonging to the preceding systole, while the pulse was absent at the instant when the next heart beat was felt.

I am, Sirs, yours faithfully,

March 30th, 1903. W. H. BROADBENT.

ANGINA PECTORIS.

To the Editors of THE LANCET.

SIRS,—In his ingenious paper on angina pectoris in THE LANCET of March 21st, p. 793, Dr. E. H Colbeck ascribes the pain experienced in the anginal paroxysm to localised [illegible] tricular wall. The chi [illegible] the pain in angina [illegible] a paper on cardiac pain and angina pectoris in the *Practitioner* for October, 1891, vol. xlvii., p. 241, is that he postulates a patchy degeneration of the ventricular wall while I assume that the symptom may be caused by weakness of the ventricular wall such as may be due to fatty degeneration either general or partial. In that paper I point out that there are probably several varieties of cardiac pain. It is not to be wondered at, however, that opinions differ very greatly in regard to their causation, because when a medical man is called in to such cases his whole attention is usually taken up by his efforts to help the patient and he has great difficulty in making accurate observations on the causation of the symptoms It is only when one has a case of frequently recurring angina under close observation, as I had in 1867, that one is able to note what changes occur in the circulation during the attack. I saw the patient almost every night for several months together and was able to notice the high blood pressure during the attack and its fall as the attack passed off. But in such favourable circumstances I was only once able to make an observation, and that an imperfect one, during its onset.

The sphygmographic tracings which I obtained showed most clearly that during an attack the pulse became small, rapid, and tense, exactly like what one would expect from a heart too weak to empty itself against the resistance of high arterial pressure. If I understand him aright says in his paper that distension of the heart and stretching of the nerve elements in the cardiac wall cannot coexist with an increased arterial pressure, but I cannot see on what grounds this statement is made. In my paper on cardiac pain and angina pectoris I have compared the pain in the heart during angina to that which occurs in the bladder or colon when these are distended and trying in vain to empty themselves. And here I may note that a sharp distinction must be made between distension and dilatation, for in all these cases it is possible for the organ to remain of its normal size or be even smaller than normal, yet be extremely distended and both its contents and its muscular walls be under great pressure because these walls are contracting firmly on the contents of the viscus. On the other hand, all three organs may be dilated much above their normal size and may not be distended at all. As I have pointed out in the paper to which I have already referred the condition which causes intense pain in the colon and bladder is an attempt of the muscular walls to expel their contents against a resistance which they are unable to overcome. Judging by analogy I consider the cardiac pain in one form at least of angina pectoris to be due to the ineffectual attempts of the heart to empty itself in face of increased arterial pressure, though how far the pain is due to distension and how far to irritation of the sensory nerves in the heart by violent contraction of its muscular fibres I cannot say. Pain will occur in the colon and bladder without any patchy degeneration of their walls. Patchy degeneration of the heart will undoubtedly enfeeble it, will give rise to inability to empty itself in face of increased arterial pressure, and may thus produce the symptoms of angina pectoris. But unless it can be shown that angina occurs only when the heart has undergone patchy degeneration and does not occur when degeneration occurs evenly over the whole ventricle, Dr. Colbeck's hypothesis, ingenious as it is, cannot be regarded as proved. In favour of the correctness of my own opinion I may adduce the fact that it led me to employ an entirely new method of treatment—namely, the lowering of arterial pressure by the administration of nitrite of amyl. I first described this method in THE LANCET of July 27th, 1867, p. 97, and the success of my plan of lowering the blood pressure either by this drug or by others which have a similar action has been conclusively proved by an experience of more than 35 years. I am, Sirs, yours faithfully,

March 25th. LAUDER BRUNTON.

THE QUARANTINE STATION AT MARSEILLES.

To the Editors of THE LANCET.

SIRS,—As one of the passengers who landed at the island of Frioul from the *Oroya* on Jan. 10th last I would like to add a few words to those of your Paris correspondent in THE LANCET of March 21st, p. 844. I preface my remarks, and I am sure all the others who were present would do the same, with an expression of profound sympathy with M. Tessier and his family in the loss which they have sustained. The death of the young man is undoubtedly due to the detention, under misrepresentation, at the lazaretto.

In addition to the defects which your correspondent notes and to the discomfort arising from the eternal mistral I particularly mention the sanitary arrangements: so disgusting were they that being a member of a profession which concerns itself with these matters, and finding no attendance, I frequently during the five days, myself, did housemaid's duty. One is bound to say that the food was good, but the place in which it was prepared was very dirty and was the common room of many undesirable persons. Of the minor discomforts and the want of the small necessities of life I do not speak; they were many and irritating, especially to the seven ladies concerned. I am sure that all present at Frioul, French, Hungarian, and English, agree with your correspondent that the quarantine station at Marseilles is a disgrace to France.—I am, Sirs, yours faithfully,

THEO. MOORE, A.R.I.B.A.

Caroline place, Mecklenburgh-square, W.C.,
March 30th, 1903.

THE TEETH OF THE PITCAIRN ISLANDERS.

To the Editors of THE LANCET.

SIRS,—In November, 1901, the daily and medical papers made comments on an interesting minute (February, 1899, and August, 1901) published by the Admiralty concerning the Pitcairn islanders. My attention was directed more especially to the details mentioned concerning the state of decay of the upper front teeth (permanent) so noticeable in many of the islanders. I wrote to the Lords of the Admiralty asking whether they would allow a series of questions concerning this feature of the teeth to be given to the medical officer of the first man-of-war which might visit Pitcairn Island. Their lordships at once agreed to this. Mr. C. S. Tomes very kindly revised a list of questions which I drew out and we then submitted the following questions (see inclosure No. 1) to be given to the medical officer of His Majesty's ship that might visit the island. The original papers were given to H.M.S. *Condor*, which vessel unfortunately was lost. Thanks to the care of the Admiralty a further copy of our questions was sent out and the following interesting communication (see inclosures Nos. 2 and 3) has been received which may be of interest to your readers.

I am, Sirs, yours faithfully.
J. KINGSTON BARTON, M.R.C.P. Lond.

London, March 29th, 1903.

[INCLOSURE NO. 1.]

QUESTIONS.

The loss of front teeth has been noted by two independent observers and among other speculative causes it has been attributed to degeneracy due to in-and-in-breeding but inadequate information is given whereon to form any opinion.

General.

1.—What proportion of the population are affected in this way?

2.—Is there any difference in the sexes in this respect?

3.—Are the back teeth also bad in the persons thus affected, or has some cause acted on the front teeth alone?

4.—Would you say that the teeth had decayed and broken off, or are they worn away?

Family.

5.—Do the families affected differ in general physique from those which are not?

6.—Are these families of European type as regards hair, features, &c., or do they show indications of admixture with Polynesian blood?

Specific.

7.—Can you learn of any habits—such as, for example, betel-nut chewing—which might influence the teeth?

8.—Or do they make any unusual use of their teeth in any of their handicrafts?

9.—Ask, in cases where the teeth are much decayed, if as an infant the child was breast fed for the usual period (six to nine months). If not, what food was given?

10.—Have you observed Hutchinson's teeth or any other marks of inherited syphilis among them?

11.—Would you say that the mental dulness noted as somewhat characteristic of the population is especially conspicuous in the persons having bad teeth?

(Signed) C. S. TOMES.
Nov. 20th, 1901. (Signed) J. KINGSTON BARTON.

[INCLOSURE NO. 2.]

To Commander C. H. Umfreville, H.M.S. *Shearwater*, Pacific Station.

H.M. Ship *Shearwater*, at sea, 17th January, 1903.

SIR,—On landing at Pitcairn Island with you on 10th January, 1903, I proceeded in pursuance of orders received to inquire into the alleged loss of the front teeth of the upper jaw amongst the inhabitants of this island. On the way from the landing place to the settlement and going through the settlement I met many of the inhabitants and was very much struck by the fact that many of them were minus the front teeth of the upper jaw.

I carried out my inquiries concerning this peculiar phenomenon on the lines suggested by Mr. Tomes and Mr. J. Kingston Barton in their letter to the Secretary of the Admiralty of 20th November, 1901. The total population of the island is 153. This number is thus made up—males 74, of whom 27 are married; females, 79. Mr. Christian very kindly collected together a number of the inhabitants for me to examine. There were present 36 in all. These 36 were a very representative gathering, as there were 14 adult males, 10 adult females, seven male children, and five female children present.

Out of this number, six men, three wome
three female children showed the remarkabl
these figures one may say that 50 per cent
and that there is practically no difference
cases, and especially in the younger people,
—i.e., the back teeth of the upper jaw and all the teeth of the lower jaw—were quite sound, in fact remarkably good. Most of the islanders had excellent teeth, barring the deficiency of the front in some cases.

The incisors are apparently the only teeth affected in this peculiar manner—at all events, that was the case in the people I saw and Mr. McCoy's testimony bears me out in this statement. These teeth break off owing to caries which sets in in childhood. Mr. McCoy informed me that this decay commences soon after the permanent teeth are established and usually first attacks one of the middle incisors. One of the children I saw was thus affected. The other incisors soon become carious and break off close to the gums. As a rule Mr. McCoy extracts the stumps. Apparently if the teeth in childhood escape the peculiar form of caries they are not thus attacked in later life. Mr. McCoy also informed me that this dental trouble made its appearance for the first time amongst the fourth generation of islanders and certainly three old men whom I saw of the third generation did not present this phenomenon. He says the children are more troubled in this way now than they were some 30 or 40 years ago.

The children of Mr. Coffin, who has been 22 years on the island, are not affected, whereas the children of Mr. Warren who settled on Pitcairn Island in 1864 were affected. Both Mr. Coffin and Mr. Warren married Pitcairn women. The families whose children are affected differ in no way, physique or otherwise, from the remainder of the [illegible] ve some members [illegible] ve the Polynesian types are equally [illegible]

THE MAKING OF POST-MORTEM EXAMINATIONS BY GENERAL PRACTITIONERS.

To the Editors of THE LANCET.

SIRS,—I feel sure that many medical men will fully agree with Dr. H. H. Littlejohn's remarks on the above subject published in THE LANCET of March 28th, p. 862. The mere fact that it is possible to obtain diplomas in medicine and surgery without having even been present at a post-mortem examination is sufficient to throw a doubt on the reliability of such examinations when made without skilled assistance. In addition to this I consider that it is work from which a general practitioner would be much better relieved seeing that he may have to go straight from a post-mortem examination to a confinement, or a compound fracture.

I am, Sirs, yours faithfully,
EDWARD H. SWEET, B.A. Oxon., M.R.C.S. Eng., L.R.C.P. Lond.
Uckfield, March 30th, 1903.

THEORIES OF IMMUNITY.

To the Editors of THE LANCET.

SIRS,—It seems to me that purely imaginary theories like that of Ehrlich are of use only if they simplify the facts which have been ascertained. The subject of immunity is one of the utmost importance and we are already in possession of many important facts in regard to it. If, therefore, Ehrlich's theory systematised these so as to give some insight into the guiding principles, so as to make the connexion between the different facts evident, so as to guide to the discovery of new facts, we might excuse its tangles of fantastic figures and erudite equations. But does it do any of these things? Dr. A. S. F. Grünbaum's explanations of Ehrlich's theories occupy your columns to-day. He tells us that a toxin molecule contains H + T + X. I can quite believe it. My acquaintance with organic chemistry would have led me to expect much more of it. But what is the use of all these cytophiles and haptophores? I may be stupid, but I cannot see it. The explanatory figures might, indeed, suggest new ideas to the designers of new carpets or wall-papers, but they do not to my mind convey a particle of useful information to a medical practitioner who wants to know enough of the processes of disease to be able to combat them.

I am, Sirs, yours faithfully,
Welbeck-street, W., March 27th, 1903. HUGH WOODS.

A DISCLAIMER AND A WARNING.

To the Editors of THE LANCET.

SIRS,—I am informed that a man of the name of "Dr. East" (or some similarly sounding name) is calling on medical men in Brighton describing himself as "Dr. Crocker's assistant" and trying to sell copies of my Atlas of Diseases of the Skin. I write to say that I know nothing of this person who is making this unauthorised use of my name and, except at the hospital, have no assistant. I may add that the Atlas is the property of the publisher and my only interest is a small royalty on each copy sold.

I am, Sirs, yours faithfully,
Harley-street, W., March 30th, 1903. H. RADCLIFFE CROCKER.

P.S.—I have since been informed that the man's name is Heath.

THE RYE AND WOOLWICH ELECTIONS.

To the Editors of THE LANCET.

SIRS,—I am obliged to you for permitting me to rectify a mistake which some of the daily papers fell into in reporting what I said about these elections at our recent conference. In referring to them I mentioned that the anti-vaccinists in both constituencies had assisted the winning members: in the case of Mr. Will Crooks because he was an anti-vaccinist and in the case of Dr. Hutchinson because he was an anti-compulsionist. As we are fighting against compulsion we can conscientiously vote for a candidate who is opposed to the present law, which inflicts fines of 20*s.* and costs for the misdemeanour of taking the advice of a qualified medical man if he advises that a child should not be vaccinated.

I am, Sirs, yours faithfully,
Edgbaston, March 31st, 1903. A. PHELPS.

⁂ The *Times* and other responsible journals reported General Phelps as claiming Dr. Hutchinson as an opponent to vaccination. General Phelps should have written to these newspapers to rectify the widespread mis-statement without waiting until his attention was called to it by us.—ED. L.

WANTED—A NEW ORDER OF NURSES.

To the Editors of THE LANCET.

SIRS,—A question which has often suggested itself to me and to others is this. At present there are, I suppose, but three kinds of nurses available in a case of sudden illness—viz., (1) the institution nurse at £2 2*s.* a week; (2) the ordinary occasional private nurse, generally a comparative amateur; and (3) the infirmary visiting nurse. But it is apparent that these three alternatives cover only half the ground. In suburban London alone there must be thousands—scores of thousands—of households where the needs are not answered by any one of the three. I mean especially the households where no servant is kept—a kind of household getting very rapidly more numerous as servants get scarcer and the already appalling bill for rent and rates gets larger. In [illegible] supplied on the understanding that she receives domestic attendance and does nothing but nurse the patient. The attendance would not be forthcoming and hence, as I say, she would not go. There remains only the private nurse. Some of these are most excellent people, but when driven into a [illegible] emergency the medical man no less than the [illegible] of a private nurse [illegible] owing prejudice in favour of more science than these nurses ordinarily possess. What I submit to be necessary and urgent is this, some institution on a large scale whence, at any time of day or night, could be got for a guinea a week a nurse who would undertake not only the bare attendance on the patient, but such additional work as the preparation of her own and the patient's food, leaving any rough work to, let us say, a charwoman. Surely there must be plenty of women skilled in nursing who would not despise an opportunity of this kind? It would be infinitely better, too, for a medical man to find a practical scientific nurse at a bedside to whom he could give his directions rather than some unskilled amateur. As to the need, it is simply a crying one. It must be borne in mind that the neighbourliness which is assumed in cases of illness and which does undoubtedly tend to solve such questions in the country is not to be relied upon in London. Every day one meets somebody who tells you that he and his wife have lived in the same suburb for so many years and "don't know their next-door neighbours," or half a dozen people in the close vicinity. Therefore I venture to ask your help.

I am, Sirs, yours faithfully,

March 3rd, 1903. R. A. R.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

More Plague Superstitions.—Improvements in Calcutta: a Serious Omission.—The Plague Epidemic: a Record in Mortality.—The St. John Ambulance Centre at Bombay.—Further Donation by Mr. Henry Phipps.—Indian Nursing Service.

EXTRAORDINARY evidence of the superstition which exists among the lower classes of the population has come to light in one of the suburbs of Bombay city where plague is raging. A woman caused a report to be made that she was possessed of a goddess and could cure plague, and having gathered a large crowd gave out that by sacrificing four sheep, two rams, and other things plague would be stopped. She also tried to do miracles, but the most ghastly proceeding was reached when she began sucking a bubo. Other cases were treated in a similar manner, by sucking or biting the bubo, applying a red powder, and pressing betel nut on the bubo with her toe. She then beat her patients with a green staff to drive out the plague, each operation lasting about 20 minutes. A considerable number of patients were treated in this manner, but the point of the story lies in the sympathy of the people and their obeisances to the woman along the public road and in the police-court. She was charged with causing a public nuisance.

The Budget estimates of the Calcutta corporation have been prepared with the object of effecting many important improvements during the ensuing year. 19 lakhs are to be spent on the suburban drainage, 13 lakhs on the continuous water-supply scheme, and no less than 70 lakhs on various public works. There are to be great extensions of roads and widening of many important thoroughfares and opening out of congested areas. Markets, slaughter-houses, and incinerators are all to be extended. In addition to the above, the great scheme for the improvement of Calcutta under a separate trust is to be taken in hand the details of which will be announced by Government shortly. Certain parts of the city of Calcutta are as bad as, if not worse than, any town in India and very widespread improvements will have to be effected to alter its insanitary condition. Perhaps the greatest fault is in the latrine accommodation for the great mass of the people, more especially in the bustees. The filthy state of the privies is general, partly because the hand removal of the excreta is very imperfect, but it is partly also due to dirty habits, to faulty construction, and to deficiency of drainage. I regret to see that nothing is reported as having been arranged to meet this most crying evil.

During the past fortnight there has occurred a record in plague mortality throughout India. Last week 28,860 deaths were reported and during the week before 27,319 deaths. The highest previous record was 26,108 in March last year. The mortality now is at the rate of over a million annually. Bombay Presidency returns 10,444 deaths, the Punjab 5642, Bengal 3436, United Provinces 3204, Central Provinces 1852, Madras Presidency 643, Mysore State 423, Hyderabad State 861, and Berar 658. Bombay city reports 1182 deaths and Calcutta 468. The epidemic is spreading in the Punjab, in Bengal, in the United Provinces, in the Central Provinces, and in Madras. The outbreaks in both Bombay city and Calcutta are developing with great intensity. In Bombay the rate of general mortality has risen to 124 per 1000 per annum. It is understood that the transfer of all plague preventive measures to the ordinary health department which is contemplated in Calcutta from July 1st next is part of a general scheme which is to be widely applied throughout India. Plague is no longer to be put on any different footing from other epidemic diseases. Such establishment as is considered necessary will be placed under the direction of the sanitary authorities.

The presentation of certificates of the St. John Ambulance Association at Bombay by H.R.H. the Duke of Connaught afforded the supporters of this movement an opportunity to announce the work which has been done on this side of India. 420 men and 158 women have earned certificates. The instruction in first-aid has been given to railway servants, soldiers, and police, both native and European. The Bombay centre has been very active and the Duke of Connaught had good reason to congratulate the staff upon the excellent work which they had accomplished. Several instances have already occurred where the instruction given has resulted in practical benefit.

It is said that Mr. Henry Phipps is so pleased with the purposes to which the Viceroy decided to devote the donation of £20,000 which he gave for the benefit of the people of India and which the Viceroy divided between a central agricultural laboratory and a Pasteur institute for southern India that he has increased his gift by another £10,000. The Government of India hopes to be able to carry out measures for combining agricultural education, scientific research, and practical experiment in one locality.

I understand that the proposed amalgamation of the Indian nursing service with the sister service at home has been abandoned. The Indian service will be strengthened during the next year by three senior nursing sisters and 13 nursing sisters.

March 6th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The General Hospital.

THIS being the season of the year at which the annual reports of the various hospitals are made public one learns the financial and general position of these institutions for the past twelve months and their needs and aspirations for the future. The General Hospital has done more work than ever during the past year, having admitted 5642 in-patients, the largest number as yet reached and 472 more than in the previous year. The cost of maintaining the hospital is great, though the expenses per head are cut down to the lowest possible figure. The chairman of the medical committee, Dr. R. M. Simon, showed that the cost per head of the in-patients was £3 5*s.* 6*d.*, as compared with £10 5*s.* at St. Bartholomew's Hospital, £7 10*s.* at St. Thomas's Hospital, £4 at the Liverpool Royal Infirmary, and the same amount at the Queen's Hospital, Birmingham. At the meeting of the subscribers to the Queen's Hospital—held shortly after that at the General Hospital, by the way—it was shown that during the past year this figure had been reduced to £3 12*s* 1*d.*, so that there is not much difference between the cost of the two institutions, both of which may be considered as being run upon the most economical lines compatible with satisfactory management. The slight excess of the Queen's Hospital over the General Hospital may easily be accounted for by the fact that the cost per head is necessarily greater in running a small than a large institution. It is not wonderful, with the increased work now being accomplished by the General Hospital, that an appeal for further funds is necessary. This institution has an annual subscription list of £7750, in addition to income from investments amounting to £6000 per annum. The subscriptions of the working men's agencies produce £3100 per annum and the average income yearly from the Hospital Sunday Fund and musical festival amounts to about £3000. The necessary annual expenditure is £25,000, so that the committee is faced with the problem of raising a sum of £5150 every year in addition to the moneys alluded to above. An important addition to the resources of the hospital will be added shortly in the shape of a laundry which is to be built and equipped at the sole expense of Sir John Holder who has for a number of years been one of the most generous friends of the institution. The most important change in the staff has been the retirement of Dr. E. Malins from the post of obstetric officer, which he has held for 25 years. He has been appointed honorary consulting obstetric officer and the vacancy caused by his retirement has been filled by the election of Dr. Thomas Wilson who has been for several years assistant in this department. For Dr. Wilson's post there are several candidates. Dr. Wilson on being appointed to this position at once resigned his post of physician to the City Hospital. There are a number of candidates for this post which should have been filled up by this time but for a slight hitch which has arisen in the proceedings. At the last meeting of the board of guardians the infirmary committee sent forward two names out of the candidates who had offered themselves for the position. For some reason this procedure did not commend itself to the board which has postponed its decision until its next meeting with a view of considering the claims of all the candidates and not merely of those recommended to it by its committee.

The Queen's Hospital.

This charity has also recently presented its report and held its annual meeting. The number of in-patients received during the year was 2365 and that of out-patients was 28,974. There was a deficit of £800 on the income and expenditure account so that further funds are here also required. During the year Mr. J. T. J. Morrison, who has been assistant surgeon for a number of years, has succeeded to the position on the full staff rendered vacant by the resignation of Mr. Frank Marsh who has been appointed a consulting surgeon. Mr. Marsh has also resigned his post as surgeon to the Ear and Throat Hospital where he has been succeeded by Dr. W. Lamb. Quite a number of junior staff appointments have been filled up, Mr. W. Billington and Mr. A. W. Nuthall having become casualty surgeons, Dr. J. G. Emanuel casualty physician, and Dr. A. S. Barnes, who has for some time occupied a resident post at the National Hospital for the Paralysed and Epileptic, Queen Square, London, pathologist. All these gentlemen were students of the local school of medicine, which may be congratulated upon having supplied this hospital with four staff officers in one year. In respect to the last appointment it may be mentioned that the wish was expressed at the annual meeting that a more adequately equipped pathological department might shortly be added to the hospital. That which it at present possesses is scarcely satisfactory and certainly falls behind the very complete provision made for this subject at the sister hospital.

The Lying-in Charity.

This body has held its annual meeting at which it was obvious that the important changes in connexion with this branch of medical work which the Midwives Act will bring about have not escaped the notice of the committee. A number of years ago there was a lying-in hospital in the city, which, by the way, was not then a city. It did not work well, or at least it was thought that its success was not sufficient to warrant its continuance and it was closed. Its museum, which contained some valuable specimens, was handed over to the medical school and now forms part of the collection in the medical department of the University. From that date the work of the charity has been purely of an out-patient character, hardly a satisfactory arrangement for so large a centre of population. The Lying-in Charity covers most of the gratuitous work of this kind in the city, for the General Hospital does not touch these cases and the Queen's Hospital has only an out-patient department for the purpose. In this last-mentioned department most of the medical students receive their training. The proposal now made by the committee of the Lying-in Charity is that a home should be erected in a central part of the city in which the secretarial and administrative work of the charity may be carried on and where also a few beds may be provided for the reception of cases requiring special treatment. It is obvious that such an institution would be very valuable, not merely to the poor, but also for the training of midwives and probably of medical students, and it is to be hoped that funds will be forthcoming for the purpose. The committee also desires to extend its present boundaries so as to make them commensurate with the enlarged boundaries of the city and to do this it must add two further districts which will involve an expenditure of £8000.

Other Hospitals.

The demands upon the generosity of the public are not exhausted by the three institutions already alluded to. The Women's Hospital requires enlargement and the Dental Hospital is crying out for a new building. For some reason this valuable institution has not received the measure of public support which it certainly deserves and so far the promises of money have not been such as to warrant the committee of the hospital in proceeding with its scheme. The amount of relief given to suffering humanity within the walls of the present building is very great and its value as the place of training of the future dental surgeons of the district is not to be underrated, so that it is much to be hoped that the very modest amount of money now asked for will soon be forthcoming in order that the new hospital may be erected.

The Education Committee.

The names of the persons who are to constitute the first education committee under the new Act have just been approved by the city council. Amongst them is the name of Mrs Ellen F. Pinsent, a paper by whom was recently published in THE LANCET on the feeble-minded children question. This lady has been a member of a hybrid committee of the late school board which deals with these cases and with those of the blind and the deaf. She has taken an extraordinary interest in the work and has devoted an immense amount of time to what is a thankless and depressing task, so that her services will be of great value to the new authority. One of the last acts of the school board was to advertise for a superintendent of the feeble-minded classes who was to be either a qualified medical woman or a woman with special knowledge of the subject. It is understood that a well-qualified medical woman is applying and it is much to be hoped that she or some similar person will be appointed, as there is no doubt that a medical training will greatly assist the occupant of the post in carrying out its duties. Such a person might also contribute to the solution of the difficult question of the best method of treatment of these cases, for it must be confessed that at present it seems as if a great deal of public money was being expended over them without any adequate return. Amongst the other names on the authority is that of one medical man, Professor B. C. A. Windle, F.R.S., Dean of the Medical Faculty in the University. He was a member of the school board for three years though he had not sought a seat upon the board which has just gone out of office.

The University of Birmingham.

A much needed addition to the medical school has been made in the shape of a large, well-lighted histology room, the old room used for this purpose being now employed for the [illegible] of experimental physiology. The new room is fitted up on [illegible] a bench supplied [illegible] office of Professor Priestley Smith, who has represented the Medical Faculty on the council of the University for the past three years, having expired, Professor H. G. Barling has been elected by his colleagues to occupy that position.—Sir Victor Horsley has consented to deliver the address at the opening of the winter session of the Medical Faculty which will take place this year on Monday, Oct. 5th.

March 31st.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Ladies' Charity and Lying-in Hospital and the Stanley Hospital.

THE annual meeting of the subscribers to the Ladies' Charity was held on March 17th, the Lord Mayor presiding. During the year 1636 patients were attended to in the outdoor department compared with 1554 in the previous year. 281 patients were admitted during the year. In connexion with the school of midwifery 43 pupil midwives were trained during the year; 37 of these entered for examination, of whom 26 received certificates of having satisfied the examiners. 32 medical students took their midwifery training with the charity during the year in accordance with arrangements made with University College to provide for this branch of the medical curriculum. £403 were received from the Hospital Saturday and Sunday Fund. There was a deficiency of over £400 in the ordinary income. The hospital was founded in 1796 and has carried on a valuable work among the poor of the city and it deserves stronger support.—A new operating theatre has become an absolute necessity at the Stanley Hospital and the committee has expressed its intention of appealing for funds to reconstruct and to furnish the operating theatre in accordance with modern ideas.

University College, Liverpool.

The council of University College has appointed Mr. D. Douglas Crawford, honorary surgeon to the Stanley Hospital, to a lectureship in surgical and applied anatomy. Mr. Douglas-Crawford received his medical education in in cases of illness and which does undoubtedly tend to solve such questions in the country is not to be relied upon in London. Every day one meets somebody who tells you that he and his wife have lived in the same suburb for so many years and "don't know their next-door neighbours," or half a dozen people in the close vicinity. Therefore I venture to ask your help. I am, Sirs, yours faithfully,

March 3rd, 1903 R. A. R.

(FROM OUR OWN CORRESPONDENT.)

The General Hospital.

THIS being the season of the year at which the annual reports of the various hospitals are made public one learns the financial and general position of these institutions for the past twelve months and their needs and aspirations for the future. The General Hospital has done more work than ever during the past year, having admitted 5642 in-patients, the largest number as yet reached and 472 more than in the previous year. The cost of maintaining the hospital is great, though the expenses per head are cut down to the lowest possible figure. The chairman of the medical committee, Dr. R. M. Simon, showed that the cost per head of the in-patients was £3 5*s.* 6*d.*, as compared with £10 5*s.* at St. Bartholomew's Hospital, £7 10*s.* at St. Thomas's Hospital, £4 at the Liverpool Royal Infirmary, and the same amount at the Queen's Hospital, Birmingham. At the meeting of the subscribers to the Queen's Hospital—held shortly after that at the General Hospital, by the way—it was shown that during the past year this figure had been reduced to £3 12*s* 1*d.*, so that there is not much difference between the cost of the two institutions, both of which may be considered as being run upon the most economical lines compatible with satisfactory management. The slight excess of the Queen's Hospital over the General Hospital may easily be accounted for by the fact that the cost per head is necessarily greater in running a small than a large institution. It is not wonderful, with the increased work now being accomplished by the General Hospital, that an appeal for further funds is necessary. This institution has an annual subscription list of £7750, in addition to income from investments amounting to £6000 per annum. The subscriptions of the working men's agencies produce £3100 per annum and the average income yearly from the Hospital Sunday Fund and musical festival amounts to about £3000. The necessary annual expenditure is £25,000, so that the committee is faced with the problem of raising a sum of £5150 every year in addition to the moneys alluded to above. An important addition to the resources of the hospital will be added shortly in the shape of a laundry which is to be built and equipped at the sole expense of Sir John Holder who has for a number of years been one of the most generous friends of the institution. The most important change in the staff has been the retirement of Dr. E. Malins from the post of obstetric officer, which he has held for 25 years. He has been appointed honorary consulting obstetric officer and the vacancy caused by his retirement has been filled by the election of Dr. Thomas Wilson who has been for several years assistant in this department. For Dr. Wilson's post there are several candidates. Dr. Wilson on being appointed to this position at once resigned his post of physician to the City Hospital. There are a number of candidates for this post which should have been filled up by this time but for a

Edinburgh, London, and Berlin and has held the post of demonstrator of anatomy at University College for several years. The new appointment has been received with much satisfaction by the students of the college, with whom Mr. Douglas-Crawford is deservedly popular.

Liverpool School of Tropical Medicine.

The Senegambia expedition of the Liverpool School of Tropical Medicine, which reached the Gambia in September, 1902, left for Senegal early in March. Dr. J. E Dutton and Dr. J. Todd have been recently making investigations into the cause of sleeping sickness at M'Carthy's Island which lies about 150 miles up the river Gambia. Bites of flies on this river are said to have caused sleeping sickness in a white man who recently died at the Liverpool School of Tropical Medicine.

The Small-pox Epidemic in Liverpool.

For the week ending March 26th 86 cases of small-pox were reported to the medical officer of health, as against 84 in the previous week. Six deaths occurred during the week. There were 321 cases in hospital, compared with 335 in the previous week.

Is a Nursing Home a Nuisance in a Residential District?

In the Lancashire Chancery Court, before Vice-Chancellor Hall, an application was made at the instance of residents in the neighbourhood for an injunction in regard to the nursing home at the corner of Ullet-road and the court was asked to decide whether a nursing home was a nuisance to a fashionable residential neighbourhood. On behalf of the defendant counsel quoted from the restrictive covenants, which said that no "art, trade, or business that could be deemed or considered a nuisance to the neighbourhood" could be carried on. That showed, he contended, that a trade or business that could not be deemed a nuisance could be carried on. He further argued that no evidence of nuisance or annoyance had been submitted. The main objection was alleged depreciation of property owing to the presence of the nursing home in the neighbourhood, but there was nothing tangible from past experience or from fears of the future to suggest that any reasonable man would be disturbed in the enjoyment of his property. He would ask the Vice-Chancellor to hold that there was no risk of infection greater than in an ordinary dwelling; in fact, the risk would be less because of the precaution taken to prevent infection. The Vice-Chancellor, in giving judgment, said that the stipulation in the covenants that nothing should be carried on that could be considered a nuisance, as alleged by the plaintiffs, implied that there might be carried on an "art, trade, or business," which could not be considered a nuisance to the neighbourhood. It seemed to him that up to the present time there had been nothing that could be considered a nuisance to the neighbourhood. No complaint had been made as to the sanitary arrangements or appliances of the home and, in his own interests, Dr. A. Stookes, the director of the home, would do all he could to guard against infection. He did not think the question which he had to try was that of the possible depreciation of the adjoining property, for anyone was entitled to use his property in an ordinary way unless he was restricted by some covenant. There was no evidence adduced of actual depreciation and he thought that the question of infection had broken down. It was obvious there was nothing like a legal nuisance. A number of people in the neighbourhood said that they were annoyed, but he was satisfied that, to any reasonable person who looked at the matter without prejudice, there was no solid ground for annoyance beyond the mere sentimental objection to such an institution being there at all. He considered that the action had failed on every ground and it would be dismissed with costs.

At the Liverpool Medical Club recently a discussion ended in the following resolution:—

> That all public hospitals ought to be taken over and managed by the State, that the expenses should be borne entirely by the State, and that the medical staff should be paid as State officers.

March 31st.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Cardiff Port Sanitary Authority.

THE importance of Cardiff as a port is incidentally indicated in the annual report of Dr. Edward Walford, medical officer of health to the port sanitary authority. In 1902 there entered the port 12,100 vessels having an aggregate tonnage of nearly 6,000,000. The six sanitary inspectors examined during the year 8179 vessels and found 1404 in a more or less defective or insanitary condition. Dr. Walford states, with evident satisfaction, that ship-owners and masters willingly carry out the recommendations of the port sanitary authority, with the result that the proportion of vessels having sanitary defects among those which frequent the port has decreased in a most marked manner. At the end of January, 1902, four men suffering from beri-beri were removed from a Norwegian barque to the seamen's hospital. The vessel sailed from Rangoon in the previous September, calling at St. Helena on Oct. 16th. The first man sickened on Nov. 29th. Several samples of food and drinking water, together with some hair from each of the four men affected, were examined for arsenic, of which there was found distinct evidence in the samples of hair but not in the food or water. No cases of plague or of suspected plague were brought to Cardiff during 1902, although 17 vessels came from places which were either infected or suspected of being infected with plague. The medical officer of health examined 707 persons on these vessels and the systematic destruction of rats resulted in the cremation of 3835.

Damages against a District Council.

A case of some importance to sanitary authorities was heard before Mr. Justice Phillimore at the Cardiff assizes on March 27th. A man living in a detached house claimed £200 damages from the Llandaff and Dinas Powis rural district council because it had neglected to empty a cesspit receiving the sewage from several neighbouring houses. The cesspit is situated near the plaintiff's house and he asserted that the noxious gases which emanated from it had seriously affected the health of one of his children. The defence of the district council was that it was not its duty to cleanse the cesspit, that it had let the work of cleansing to a contractor, whereupon its liability ceased, and finally that the cesspit had been cleansed and any nuisance arising from it was due to defective construction. Judgment was given for the plaintiff for £30 and costs and an injunction was granted restraining the district council from permitting the continuance of the nuisance. The injunction was suspended pending an appeal by the council.

Bristol Royal Infirmary.

The annual meeting of the subscribers to this institution was held on March 25th, Sir Charles Cave presiding. The medical report stated that during 1902 the in-patients numbered 3281, against 3246 in 1901. 41,761 out-patients were treated, compared with 41,863 in the previous year. 531 patients were sent to the Victoria Jubilee Convalescent Home—an increase of 114 over 1901. The financial statement showed that the total ordinary income amounted to £11,125, against £11,467 in the previous year. The total ordinary expenditure was £15,415, compared with £15,252 in 1901. The total adverse balance against the institution now amounts to £11,253. The report, in alluding to the annual deficiency in the working of the infirmary, adds that unless greatly increased financial support is forthcoming the committee will be obliged to reduce the work of Bristol's oldest medical charity.

Bristol Workhouse Infirmary.

Reference has already been made in THE LANCET of Oct. 4th, 1902, p. 962, to the extremely unsatisfactory accommodation provided by the Bristol board of guardians for the sick poor and imbeciles under its care. With the exception of 36 beds in a stone building and the maternity wards the whole of the infirmary accommodation at the Eastville workhouse consists of wooden buildings or of corrugated iron buildings lined with wood and felt. Nearly 150 more or less helpless patients are housed in these erections. Mr. E. B. Wethered, an inspector of the Local Government Board, has recently reported in very strong terms upon the dangerous character of the buildings and expressed the opinion that in the event of a fire occurring it would be practically impossible for the occupants of the wards to be rescued without loss of life. In a letter to the board of guardians forwarding this report the Local Government Board states that it cannot take the responsibility of allowing the use of the present buildings for a longer time than is absolutely necessary to enable suitable infirmary buildings of a permanent character to be provided. Land has already been secured for the erection of an infirmary sufficient for the needs of the entire union, detailed plans have been drawn, and as long ago as obtained." The Local Government Board has placed the County Antrim Infirmary on its list of hospitals the training of which gives the status of "qualified nurses" for union hospitals in Ireland.

April 1st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Acoustics of the Great Hall of the Academy of Medicine.

AT a sitting *in camerâ* of the Academy of Medicine which was held on March 17th, M. Javal read a report on the acoustics of the great hall of the Academy of Medicine. The report had been drawn up by the section of Physics and Chemistry. He mentioned in his report that the commission which had been appointed to consider the matter came at once to a unanimous conclusion. The commission has formulated various propositions for diminishing the excessive echo and recommends that those should first be carried out which will entail but little expense. It recommends that the speaker's platform should be placed on the right side of the hall. It was so placed on the opening day and everyone present was able to hear with perfect distinctness the report which was read by the secretary from the platform when in this position. The commission also recommends that the bottom of the hall should be hung with drapery for the time being, that the floor should be covered with a thick carpet, and that underneath the sky-light cotton threads which would hardly be seen should be stretched. In this way it is probable that the constant echoes of sounds produced in the hall would be much lessened. At present the sound waves are reflected at varying angles from the floor to the sky-light and to the walls and back again and vibrations are set up in the thick glass of the sky-light and in the xylolith which covers the flooring. The commission also recommends that the lamps hanging from the ceiling should be removed, as those at the desks give quite light enough. The panes of the sky-light should be of very thin glass. Finally, the commission recommends that the four seats at present occupying the upper part of the central gangway should be removed as they render exit difficult and are thus the cause of noise; moreover, the small rooms on the ground floor should be shut off by curtains.

Oxygenated Water.

At the meeting of the Academy of Medicine held on the same day M. Lucas-Championnière laid before the meeting some researches by M. Maget and M. Planté on the Use of Oxygenated Water employed as a Spray for the Disinfection of Tortuous Cavities. It was thought that the heating and the nebulisation of the solution would cause it to lose most of its oxygen and, consequently, most of its disinfective power; as a matter of fact, the spray of oxygenated water contains only a portion of the oxygen contained in the original solution M. Maget and M Planté sought by experiment to discover how much oxygen was lost by distillation and they found that in oxygenated waters (solution of hydrogen peroxide) containing from nine to 11 volumes of oxygen the distillate contained from 0·20 to four volumes of oxygen. The average quantity found in the distillate varied between one and two volumes. Although from these results it may be estimated that the quantity of oxygen in the spray would be but small yet there is enough to give it a real therapeutic value. M. Lucas-Championnière performed some control experiments and found that his results on the whole were comparable to those of M. Maget and M. Planté. As a rule though, he obtained smaller quantities of oxygen in his distillate than they did. M Lucas-Championnière considers that the net result of all the experiments is to show that solutions of hydrogen peroxide have a real therapeutic value, even when used as spray.

The Treatment of Lead Colic by Electric Rectal Injections.

At the meeting of the Hospitals Medical Society held on March 20th M. Galliard read a note upon the above-mentioned subject. He had had a patient under his care in whom it was doubtful whether the diagnosis should be lead colic or appendicitis. The patient had had no motion of the bowels for five days and for 36 hours had not even passed any flatus, so M. Galliard determined to try an electric rectal injection. The success of this treatment was very rapid and so M. Galliard determined to try it on three other patients who were undoubtedly suffering from lead colic. In all three the treatment acted well, the pains ceased, and the bowels rapidly regained their power after one or more electric injections. M. Galliard considers that this method of treatment is preferable to the purgatives which are generally used, for these latter are, as a rule, not well borne and in addition are very prone to irritate the intestinal mucous membrane. M. Moutard-Martin, in his speech on the matter, said that in his opinion if these electric injections could be employed without danger in cases of lead poisoning they must, on the other hand, be forbidden in cases where there was reason to suspect the existence of appendicitis.

The Operative Treatment of Irreducible Dislocations of the Elbow joint.

At the meeting of the Surgical Society held on March 25th M. Picqué, speaking on the operative treatment of irreducible dislocations of the elbow-joint, said that he had always been an advocate for resection as against simple incision (*arthrotomie*), of which the results were generally bad. M. Picqué always uses a median posterior incision which divides the triceps and which necessitates freeing that muscle at its insertion into the olecranon. He had never found any inconvenience result with regard to the future capability for use of the limb It is true, however, that operating with this incision presents more difficulty than when other incisions are used, for when it is used it is by no means easy to free the lower end of the humerus from the tough fibrous adhesions which surround it. With regard to his latter point, M. Picqué thinks that very possibly operation by lateral incisions offers some advantages.

Obituary.

French science has suffered a severe loss by the death, which occurred recently, of Dr. Georges Bouilly, surgeon to the Cochin Hospital. He was 54 years of age and succumbed after a long and painful illness. He was one of the most skilled gynæcologists of the day, and although he was not spared to publish the great treatise on gynæcology which he had in preparation, yet he had written much in the various reviews on particular points of his specialty.

March 31st.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Medical Profession and the Sick Clubs.

THE Deutscher Aerztevereinsbund, or German Medical Practitioners' Association, held an extraordinary meeting in Berlin on March 7th, Professor Löbker of Bochum being in the chair. The meeting was attended by 347 delegates from every part of Germany, representing about 19,000 medical men. It was convened principally for the purpose of protesting (1) against the new Bill relative to the insurance of workmen; and (2) against the habitual indifference displayed by the Government towards the wishes of the medical profession. Professor L [illegible] bject said that although legislati [illegible] clubs and to the insurance of [illegible] involved questions possessing an obvious interest for medical practitioners the Government had taken no steps whatever to ascertain their views as to the manner in which they might be affected by the various enactments and seeing themselves thus ignored in matters which deeply concerned them it was desirable that they should consider what course was requisite for resisting encroachment and protecting their interests. Their patience was rapidly becoming exhausted and there was every probability that without their coöperation the scheme for the insurance of workmen would fail. In the discussion the "free choice system" in club practice was generally recommended as supplying the relatively best protection against the high handedness of the clubs and in conclusion a resolution to the following effect was unanimously adopted:—

[illegible]

The meeting was evidently disposed to uphold [illegible] just rights of medical practitioners The success of the strike of medical men at Gera (to which allusion was [illegible] in and Apportionment of New York has appropriated the sum of $3,000,000 (£600,000) to be expended in constructing a new Bellevue Hospital and a sum of $500,000 (£100,000) has also been appropriated for new buildings for Fordham Hospital. Both of these hospitals are city charitable institutions. It seems that New York will at last have public charity hospitals in keeping with her wealth and size. The management of Bellevue Hospital and the allied city hospitals is said to have much improved under the new *régime*.

New York State Nurses Bill.

An amendment to the Public Health Law of New York State is now before its Legislature. The new Bill provides for the appointment of a board of examiners by the regents of the University of the State of New York who shall test the fitness of candidates to register as nurses. A candidate in order to be eligible for examination must be over the age of 21 years, of good moral character, and must hold a diploma from a training school for nurses connected with a hospital giving a course of at least two years. Eligible candidates after having passed the examination will be granted a certificate by the regents which will authorise them to practise as, and to style themselves, registered nurses, but no other person may assume this title. Upon recommendation of the board of examiners the regents of the State of New York may in their discretion waive the examination of any persons possessing the afore-mentioned qualifications who shall have graduated before, or who are in training at the time of, the passage of this Bill and who shall apply in writing for such certificate within three years after the passage of this Bill. It is hoped that this Bill, if passed, will put an end to many of the abuses which now exist in New York State with regard to so-called trained nurses.

March 24th.

Obituary.

THOMAS JOHN MACLAGAN, M.D. EDIN., M.R.C.P. LOND.

IN the last issue of THE LANCET we recorded the death of Dr. Thomas John Maclagan, which took place on March 20th at his residence, 9, Cadogan-place, S.W. Dr. Maclagan received his medical education at the University of Edinburgh where he graduated M.D. in 1860, but he afterwards studied at Paris, Munich, and Vienna, and after some time spent in Dundee finally settled down to practise in London. He was physician-in-ordinary to their Royal Highnesses the Prince and Princess Christian of Schleswig-Holstein and was also for some time examiner in medicine at the University of Aberdeen. He is best known to the medical profession by his work on rheumatism and as the introducer, or rather renewer, of salicin in the treatment of that disease. The use of this drug he described in THE LANCET of March 4th (p. 342) and 11th (p. 383), 1876. In view of the most modern theories as to the cause of rheumatism it is interesting to note that Dr. Maclagan in 1876 wrote as follows: "Rheumatic fever is nowadays generally regarded as being produced by some cause or agency which is generated within the body. My own investigations into its pathology have led me to reject this view and to adopt the old 'miasmatic' view of its mode of origin, according to which the cause which gives rise to the disease is introduced into the system from without." Arguing from this idea and from the idea that as the cinchonaceæ grew most plentifully in regions where malaria prevailed so also possibly some plant which grew plentifully in regions where the "rheumatic miasm seemed most to prevail" would prove effective, he was led to try the salicaceæ. Decoction of willow bark had, of course, been known as a "cure" for rheumatism for many years previous to 1876 and the use of salicin is nowadays almost superseded by the salicylates, but still Dr. Maclagan would seem to have been the first to draw the attention of the medical profession to the use of salicin in modern days. His views as set forth in the paper from which we have quoted were afterwards expanded in a book entitled "Rheumatism, its Nature, Pathology, and successful Treatment." Dr. Maclagan has left a widow, three sons, and a daughter. His body was buried on March 24th at Woking, the first part of the burial service being said at St. Paul's, Knightsbridge.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Crolas, professor of pharmacology in the Medical Faculty of Lyons.—Dr. Bonamy, chief medical officer of the Nantes hospitals.—Dr. Juán Giné y Partagas, professor of external pathology in Barcelona, and one of the most eminent surgeons in Spain.—Dr. Raingeard, surgeon to the Nantes hospitals.—Dr. F. Cramer of Wiesbaden, formerly assistant to Professor von Langenbeck.—Dr. Julius Victor Carns, professor of zoology in Leipsic, in his eightieth year. He was for a short time some 50 years ago curator of the Comparative Anatomy Museum, Oxford.—Dr. T. G. Thomas, formerly professor of gynæcology and obstetrics in the New York College of Physicians and Surgeons.—Dr. M. Crisafulli, professor of clinical medicine in the Messina Medical School.—Dr. Bouilly, surgeon to the Paris hospitals.—Dr. Fritz Stockmann of Königsberg, author of many papers on renal diseases.—Dr. Walther Ruschaupt, assistant in the Breslau Pharmacological Institute.

Medical News.

UNIVERSITY OF ABERDEEN.—The following candidates were successful in the examinations indicated:—

I. (*a*) *First Professional Examination.*—Henry Begg, William Begg, Francis J. Browne, James M'K. Clark, George Cooper, James Donaldson, Robert J. Duthie, Herbert W. Glashan, Stephen Goodbrand, Alfred P. Hall, Leighton H. Hay, Dalziel B. M'Grigor, James R. M'Kenzie, Douglas J. Marr, John H. Moir, Alexander Noble, A. N. E. Rodgers, David M'D. Roger, Henry Smit, Frank P. Sturm, Robert Watson, and William A. Watson.

(*b*) *First Part of the First Professional Examination.*—Thomas Clapperton, Andrew L. E. F. Coleman, Thomas Donaldson, Theodore G. Gray, George H. C. Lumsden, Robert W. Macpherson, Angus Macrae, George Mitchell, John J. A. Neil, Robert Ross, and Ernest Walker.

II. (*a*) *Second Professional Examination.*—Mary R. Bisset, *Robert Brown, William Campbell, Alexander Dawson, Hubert K. W. H. Dornhorst, Robert R. Duncan, William G. Gordon, Neil Kennedy, Alexander W. Laing, William Low, James B. Macdiarmid, Roderick Mackay, James Mackenzie, Kenneth Mackinnon, George Milne, Alexander Mitchell, Harry R. Neilson, Alexander D. Pringle, John Proctor, *William E. Reid, James Silver, James A. B. Sim, *Robert H. Spittal, John Herbert Stephen, Isaac F. B. de Villiers, *Frederick H. Welsh, and Lisette A. M. Wilson.

(*b*) *First Part of the Second Professional Examination.*—James Adams, Alexander Brown, Charles B. Gerrard, James M'Intosh, John A. Milne, Paul B. Roth, John Sangster, and Robert N. Thomson.

III. (*a*) *Third Professio* [illegible] F. Anderson,
Francis Anderson, Jo [illegible] William R.
Catto, Alexander G. [illegible] Davidson,
Alexander Duguid, Al [illegible] eorge Hall,
Alexander Hendry, Jol [illegible] Thomas C.
Innes, Herbert M. Ja [illegible] Hernaman
Johnson, *Frederick [illegible] on, Donald
Mackay, Malcolm Mac [illegible] chael B. H.
Ritchie, James Rober [illegible] rtie R. G.
Russell, Herbert W. [illegible] M. Smith,
John M. Taylor, and *William Wood.

(*b*) *First Part of the Third Professional Examination.*—George Adam, Walker A. Elwood, and James H. Thomson.

IV. *Fourth Professional Examination:* (*a*) *Degree of M.B., Ch.B.* (New Regulations).—William Anderson (Kinbore), Frank W. Begg, Hugh S. Brander, Arthur J. Grant, Charles W. F. Gray, John J. Harris, George Hendry, George G. Macdonald, James F. M'Intosh, John A. M'Kenzie, *Hugh Maclean, Gordon W. Maconochie, William Mearns, Kenneth S. Melvin, George Mitchell, Andrew B. Morris, William F. Munro, Adam S. Niven, Alastair G. Peter, William R. Pirie, James H. Shepherd, Frederick K. Smith, William Stewart, George Stoddart, Cornelius A. Suvoong, and William A. Watson.

(*b*) *Degree of M.B., C.M.* (Old Regulations).—John Fraser and Julius E. Perera.

* Passed with distinction. † Passed with much distinction.

TRINITY COLLEGE, DUBLIN.—At examinations held recently the following candidates were successful:—

Diploma in Public Health, Part I.—George Raymond, Thomas G. Moorhead, Kingsmill W. Jones, Albert L. Hoops, Walter C. Oram, John N. Laird, Robert G. H. Tate, and Thomas F. Telford.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following candidates have passed the Primary part of the Fellowship examination:—

W. W. Boyce, R. A. Brown, R. Bury, J. S. Dunne, G. H. Gallagher, and J. M. Hayes.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Bernhard Heine has been recognised as *privat-docent* of Otology and Dr. Paul Schuster as *privat-docent* of Diseases of the Nervous System.—*Bologna :* Dr. Lodovico Beccari has [illegible] Forensic Medicine. [illegible] sition as Extra- [illegible] August Luxen- [illegible] of Surgery.—*Naples :* Dr. Teodorico Rosati of Rome has been recognised as *privat-docent* of Laryngology and Otology.

ROYAL INSTITUTION.—The following are among the lecture arrangements at the Royal Institution after Easter:—Dr. Allan Macfadyen, three lectures on the Blood and some of its Problems; Professor G. H. Darwin, two lectures on the Astronomical Influence of the Tides (the Tyndall lectures); Professor E. J. Garwood, two lectures on the Work of Ice as a Geological Agent; Professor Dewar, three lectures on Hydrogen—Gaseous, Liquid, and Solid; Professor S. H. Vines, two lectures on Proteid Digestion in Plants; and Professor Silvanus P. Thompson, two lectures on the De Magnete and its Author, (1) the Book, and (2) the Man. The Friday evening meetings will be resumed on April 24th.

DONATIONS AND BEQUESTS.—Under the will of Mr. Henry Baker Hicks of Bristol, after the death of his widow, the following legacies are to be paid: to the Bristol Eye Hospital, £100; to the Bristol Dispensary, £150; and the Bristol Royal Infirmary and the Bristol General Hospital will each receive £1000.—The Pendlebury Hospital for Children, Manchester, the Manchester Hospital for Consumption and Diseases of the Throat and Chest, and the Northern Counties Hospital for Chronic and Incurable Diseases will each receive £500 under the will of Mr. F. Boden Benger of Knutsford.—Mr. J. McIntyre, M.D. St. And., has by his will bequeathed £1000 to the Royal Medical Benevolent College Pensioners' Fund and a like sum for a cottage hospital at Odiham, Hants.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—Mr. Colston Wintle, L.R.C.P. Lond., M.R.C.S. Eng., on March 16th was presented with a timepiece at the first annual dinner of the Horfield and Bishopston (Bristol) Horticultural, Feather and Fur Association in recognition of his labours on behalf of the association and its exhibition.—The members of the Cockington (Torquay) Men's Branch of the St. John Ambulance Association have presented Mr. George Henry Cressey, L.R.C.P. Lond., M.R.C.S. Eng., with a surgical electric lamp as a mark of appreciation for his services as honorary lecturer.—Mr. W. Ffennell MacCarthy, M.D. Dub., who has recently resigned the office of surgeon to the Sir John Moore Lodge of Oddfellows (Worcester Branch) after 20 years' service, was on March 23rd presented with a framed illuminated testimonial by the members of the lodge.

ACTION TO RECOVER MEDICAL FEES.—At the Wolverhampton county court on March 27th Mr. Thomas Wolverson brought an action to recover £4 19*s*., being his fees for medical attendance on a family. On Nov. 28th, 1902, two of the children fell ill with scarlet fever and the parents were advised by both the plaintiff and his son, Mr. John A. Wolverson, to have them removed to the isolation hospital, but the recommendation was not followed. On Dec. 21st the defendant's wife fell ill and he thereupon called in Dr. Edwin Morton who came to the conclusion that the children and their mother suffered from diphtheria and not from scarlet fever. Mr. Wolverson was then informed that his services, which had been retained for the approaching confinement of the defendant's wife, would not now be required and payment of his account was refused on the ground of unskilful treatment. At the trial the question of diagnosis was not pressed, the defence now alleging that the plaintiff ought to have advised the family to quit the house as the drains were out of order. In the result the judge said that the plaintiff had advised the defendant to complain to the sanitary authorities about the drains. He came to the conclusion that the children were properly treated and he gave judgment in the plaintiff's favour for the amount claimed. The plaintiff's case was managed by the Medical Defence Union.

ROYAL DENTAL HOSPITAL.—The annual general meeting of governors was held at the hospital, Leicester-square, on March 31st, Lord Kinnaird being in the chair. The committee of management reported a very large increase in the number of patients during the past year, there being 15,244 more cases treated than in 1901 and a corresponding increase in the working expenses. The consent of the Charity Commissioners and of the Prudential Assurance Company, which holds a mortgage on the property, having been obtained, the "Duke's Head," a public-house on the premises, has been closed as a public house and the licence destroyed. The friends of the hospital must not let the charity be a loser *by this step.*

UNIVERSITY OF LONDON.—A meeting of the Faculty of Medicine was held at the University, South Kensington, on March 27th, Mr. Henry T. Butlin, the Dean of the Faculty, being in the chair. Dr. J. Rose Bradford and Dr. J. Kingston Fowler were unanimously re-elected as representatives of the Faculty upon the Senate. In thanking the Faculty for the renewed expression of its confidence, Dr. Fowler referred to the fact that the work of the Senate in reorganising the curriculum and scheme of examinations for degrees in medicine and surgery was practically completed and stated that the new regulations shortly to be issued would be found to contain most of the modifications recommended by the Faculty. He felt sure that the Faculty would be gratified by the announcement made at the last meeting of the Senate that their Royal Highnesses the Prince and Princess of Wales had signified their willingness to accept the honorary degrees of Doctor of Law and Doctor of Music respectively. The Dean presented a report showing that satisfactory progress had been made in the negotiations between the Senate and the Faculty with regard to the establishment of a university institute to provide common courses of instruction for internal students and others in the preliminary and intermediate subjects of medical education.

THE MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—The annual general meeting of the Medical Graduates' College and Polyclinic was held at the college, 22, Chenies-street, [illegible] H. Broadbent, Bart [illegible] those present were [illegible] Taylor, the honorary treasurer, and Captain A. E. Hayward Pinch, I.M.S., the medical superintendent. The report showed that the number of members and subscribers had increased from 825 in 1901 to 941 and an increase was noted in all departments of the college work. The chairman, in moving the adoption of the report, pointed out that every year brought something new which was worthy of the attention of practitioners. Blood examinations had now become matters of extreme importance, for examination of the blood told them much about clinical diseases. In all these matters great light had been thrown upon disease and great aid was obtained in treatment. The consultations carried on at the Polyclinic were interesting, but were a poor substitute for the kind of work that ought to be carried on. He had never ceased to hope that sooner or later they would have a [illegible] tions [illegible] on the [illegible] Hospital was endeavouring to meet this kind of want and it had their sympathy in the work it was trying to carry out. Referring to the composite course of lectures in medicine and surgery he said that they seemed to him of great service, but his only fear about them was lest they should swamp the clinical teaching. Lectures, however good, were not the best kind of teaching unless they were associated with demonstrations affording objective teaching. Sir William Kynsey seconded the motion. Dr. Seymour Taylor, the honorary treasurer, said that *the institution needed money* and unless it was obtained they would have to close their doors. A proposal was then made that members should pay two guineas per annum instead of one as at present. The chairman said that he thought that if the subscription were raised the financial question would be solved. He did not think that there was any great risk of catastrophe. The report and balance sheets were adopted.

Dr. Robert [illegible] Library

Parliamentary Intelligence.

HOUSE OF LORDS.

THURSDAY, MARCH 26TH.

Physical Tests for Army Recruits.

The Earl of **HARDWICKE**, Under-Secretary of State for War, in answer to a series of questions on this subject said that the present standard of height for recruits entering the infantry of the line was 5 feet 3 inches; it was the same in January, 1899. He could not give the average chest measurement of recruits during the past year, because a new system had been introduced. Under the old system no recruit was accepted, except as a special, whose minimum chest measurement was less than 33 inches. But in accordance with the report of a committee of military and civilian doctors another system was introduced on April 1 last year. The chest was measured first when fully expanded; secondly, when relaxed; and if there was a difference of not less than two inches between the two measurements the recruit was accepted, whereas if it were less than two inches he was not accepted. Since the introduction of this system no man had been accepted who did not comply with those conditions. In future it was intended to issue a return showing the average height, chest measurement, and the weight of every recruit on enlistment. Then after he had completed six months' service and gone through gymnastic training he would again be measured and if he had not, according to the requirements laid down by the committee, increased his physical development to the extent considered necessary he would not be allowed to remain in the army.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 25TH.

The Royal Commission on Tuberculosis.

Mr. **LONG**, in reply to Mr. **FIELD**, said he was informed that it was impossible to state definitely at present when the report of the Royal Commission on Tuberculosis would be issued.

THURSDAY, MARCH 26TH.

The Sale of Poisons.

Mr. **JAMES O'CONNOR** asked the Home Secretary whether he would consider the advisability of introducing a Bill for the purpose of increasing the restrictions upon the sale of poisons.—Mr. **AKERS-DOUGLAS** replied: The hon. Member will be aware that a departmental [illegible] Lord President recently reported upon [illegible] the sale of poisons. That report is now [illegible] Some of the recommendations of the committee are in the direction indicated in the hon. Member's question.

The Quality of Alcoholic Liquors.

Mr. T. M. **HEALY** asked the Chancellor of the Exchequer if he would say what supervision, if any, the Government exercised in regard to the nature and quality of the whisky and other spirits consumed by the public; if he had any official reports showing that the increase of lunacy and crime in this country was largely due to bad drink now being sold as genuine malt whisky and brandy; whether he would cause inquiries to be made as to the laws in force in other countries for the protection of the public against the sale of deleterious blends and other objectionable alcoholic liquors; whether the Excise Department possessed a record of the materials used in distillation by every distillery in the three kingdoms; and, if so, whether he would grant a return showing the nature of those materials used by each distiller for the year 1902.—Mr. **RITCHIE** replied: The Government does not exercise any supervision as regards the nature and quality of the whisky and other spirits consumed by the public, the provisions of the Sale of Food and Drugs Act in this connexion being administered by the local authorities. I am not aware of any such reports as those to which the hon. and learned Member refers and I do not think that a return of the legislation in other countries would be likely to serve any useful purpose. The revenue authorities possess a record of materials used in distillation, and the totals are published annually in the statistical abstract. A return of the materials used by each individual distiller would be a very invidious one, and I cannot think it desirable.—Mr. **HEALY**: Does not the right hon. gentleman consider that the fact of such a return being invidious is the very reason why it ought to be published? Then the honest man would have a chance.—Mr. **RITCHIE**: I have no doubt that individual purchasers can easily protect themselves if they choose to go the right way about it.—Mr. **HEALY** asked the right hon. gentleman whether he had any official reports showing that guarantees and statements as to age affixed by blenders to whisky bottled in bond were often false or exaggerated, and, if so, whether he would explain why such marking of whisky was allowed under Government auspices where age was a vital point; why the Revenue Boards of Customs and Excise refused to guarantee officially the age of whisky bottled in bond which they knew to be correct but allowed incorrect descriptions to be used by blenders; whether he was aware that certificates of analysis from leading analysts to give colour to frauds were often placed on the bottles, also under Government supervision; and whether he would issue instructions to put an end to all these practices in Government warehouses?—Mr. **RITCHIE** replied: I am not aware of any such official reports as those to which the hon. and learned member refers. The question of exercising control over labels affixed to goods in bond is one which cannot possibly be adequately discussed within the limits of an answer to a question. The practice of the Revenue Boards is to limit themselves almost entirely to prohibiting the use of labels implying any Government guarantee of accuracy, and to preventing any gross misdescription of foreign spirits as British and *vice versâ*. I cannot undertake to alter this practice, for the reason (amongst others) that the moment spirits have been taken out of bond the control exercised by the boards must cease.—Mr. **HEALY** said that a predecessor of the right hon. gentleman some 12 or 15 years ago appointed a select committee to go into this subject and he asked whether the right hon. gentleman would now grant a departmental committee or a committee of the House to make some fresh inquiry into the new evils which had arisen.—The **CHANCELLOR** of the **EXCHEQUER**: I shall always be willing to consider representations that may be made with regard to inquiries into this or any other matter. If any further communication between the hon. and learned gentleman and myself should lead me to believe that some good could be accomplished I should be pleased to entertain his suggestion.

The Military Hospital at Alton.

Questions were addressed to the Secretary of State for War as to this hospital, built during the war with money subscribed by the public.—Mr. **BRODRICK** explained that there had been delay caused by [illegible] terms on which the hospital would be handed [illegible] in this connexion had now been overcome and [illegible] that the building would be used as a permanent hospital.

The Medical Service of the Navy.

On the vote for the medical establishments and services of the navy Mr. **KEARLEY** suggested that instructi [illegible] work to men of all classes in the navy [illegible] had taken any steps to secure a rese [illegible] war.—Sir **JOHN COLOMB** supported the suggestion as to instruction in ambulance work.—Mr. **ARNOLD FORSTER**, Secretary to the Admiralty, said that it had been under consideration whether more instruction in ambulance work might not be given in the navy, and steps had been taken to increase the hospital staff and sick bed attendance in time of war by the employment of volunteers. The question of a reserve of doctors had not escaped the attention of the Admiralty. As a matter of fact, steps had already been taken to institute such a reserve and they had had a most gratifying response from the medical profession; a large number of medical men had already signified their willingness to undertake duty under the conditions laid down by the Admiralty.—Mr. **GROVES** raised the question of members of the Navy Medical Service being given opportunity from time to time for bringing themselves up-to-date with modern treatment.—Mr. **ARNOLD FORSTER** said that the Admiralty considered it very important that their medical officers should have this up-to-date training and in order that they might obtain it the Admiralty had received the sanction of the Treasury to make provision for not less than 50 medical officers each year to attend post-graduate courses of instruction at medical schools.

Vaccination and Government Service.

Mr. **CORRIE GRANT** asked the Secretary of State for War whether he was aware that clerks of works on the Royal Engineer civil staff had been ordered to be vaccinated on penalty of dismissal, and if so, would he state whether this order had been issued with his sanction.—Mr. **BRODRICK** replied: Nothing is known of any such specific cases. The general officer commanding the Home District issued orders about a year ago during the small-pox epidemic that such clerks were not to be taken on if they refused vaccination.

FRIDAY, MARCH 27TH.

Vaccination Proceedings.

Sir **CHARLES M'LAREN** asked the President of the Local Government Board if his attention had been called to representations of the Hinckley guardians as to the state of the law as to the control of vaccination officers; and whether he would take steps to prevent these officials engaging legal advisers without consultation with or the consent of the guardians.—Mr. **LONG** replied: My attention has been called to representations made by the guardians on the subject. As regards the last part of the question, I must point out that the duty of the vaccination officer [illegible] cases of default is quite independent of any direct [illegible] In cases where th guardians are opposed to [illegible] Vaccination Acts it would obviously be impos [illegible] officer to carry out the duty referred to if he had to obtain the consent of the guardi to the legal assistance which was requisite for the purpose, and I am advised that it is a necessary incident of the statutory duty of vaccination officer that he should have authority to engage legal assistance where this is required.

MONDAY, MARCH 30TH.

Poor-law Administration in Ireland; Commission to be Appointed.

Dr. **THOMPSON** as [illegible] Ireland if he would [illegible] to inquire into the [illegible] also into the question of the administration of the Poor-law, [illegible] dition of the workhouses, and [illegible] management of t [illegible] poor in these institutions.—[illegible] Government [illegible] about to appoint a commissio [illegible] question of [illegible] amalgamation of unions and [illegible] condition of [illegible] classes of destitute poor in [illegible] ce of the Ir [illegible] Poor-law medical officers, whi [illegible] the ratepay [illegible] expense, [illegible] the law on t [illegible] subject w [illegible] see it bro [illegible] hoped to [illegible]

TUESDAY, MARCH 31ST.

Sale of Adulterated Butter Bill.

This Bill was read a second time and referred to the Grand Co mittee on Trade. In the course of the debate Mr. **HANBURY**, t Minister in charge of the Bill, undertook to consider whether, inste of saying that butter containing 20 per cent. of moisture should not sold and that the presence of 16 per cent. should create a presumpti in favour of adulteration, there should be inserted a standard of 18 p cent. applicable all round. He also undertook to consider whether was desirable in the public interest to have milk-blended bu labeled as the Bill proposed as [illegible] "blended" butter. On the wh the Bill was well received by [illegible] likely that it will be conside [illegible] stage. Committee or when it comes bac [illegible]

The Volunteer Medical Service.

Mr. **REMNANT** asked the First Lord of the Treasury if he would con sider the advisability of including a volunteer medical officer am the members of th [illegible] appointed to consider t Volunteer Service. [illegible] fear I cannot promise include officers of [illegible] rps on the commission.

Royal Army Medical Corps.

Dr. **THOMPSON** asked the Secretary of State for War if he was a

DEATHS.

BARLOW.—On March 27th, at Orlebar, St. Peter's, Kent, Robert Barlow, M.R.C.S., aged 64 years.

HUGO.—On March 29th, at New Brompton, Kent, Edward Henry Hugo, L.R.C.P. Lond., M.R.C.S., L.S.A., in his 69th year.

HUNTER.—On March 25th, at Abercromby place, Edinburgh, James Adam Hunter, M.D. Edin., F.R.C.S. Edin., in his 80th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

TO MEDICAL FREEMASONS.

WE are asked to publish the following appeal:—The executors of the late Lieutenant-Colonel S. J. Flood, R.A.M.C. (Dr. Richard Flood of Bundoran and Mr. Arthur Tuffield of 5, Brunswick place, Cambridge) earnestly appeal to all medical Freemasons, and especially to those connected with the Royal Army Medical Corps, to give their votes to Samuel Basil Flood, youngest son of the above mentioned Lieutenant-Colonel Flood, at the April election to the Royal Masonic Institution for Boys, for although he obtained 3226 votes he was unsuccessful in October last. The late Lieutenant-Colonel Flood had seen much active service on the West Coast of Africa; he was a most ardent Freemason, having been connected with many lodges *in this country and in India. He died at the early age of 42 years*, leaving four young children very inadequately provided for. Votes will be gratefully received by Arthur Tuffield, 5, Brunswick-place, Cambridge.

LUKE writes: I do not know whether any steps have yet been taken to save the great wastage which there is in the medical votes for the Masonic charities. It is most desirable that some organisation should be initiated in this respect seeing that the profession always has been (*teste* Mr. R. F. Gould), is, and in the future will be to an infinitely greater extent (by reason of the establishment and popularity of medical lodges and especially of lodges founded in connexion with the great hospitals), a powerful factor in Freemasonry. I do not for a moment suggest that medical cases, simply because they are *medical* cases, should be given preference when any particular medical voter is personally interested in any particular case, but I do urge the creation of some organisation by means of which medical Freemasons who do not happen to be interested personally or through their friends in any candidate (and this must constantly happen) may know how best to dispose of their votes in relief of some distressed child of a brother practitioner and in the case of there being several medical candidates that they may be able to ascertain which case is in most pressing need of assistance. My immediate object, however, is to ask to be permitted to point out in the columns of THE LANCET that in the voting papers just issued occur the names of three medical candidates, namely, for the Royal Masonic Institution for Boys Samuel Basil Flood (with 3226 votes brought forward) and Cyril Patrick Hines (with 994 votes brought forward)—the name of the latter will be removed from the list of candidates if unsuccessful at this election under a law limiting the age of candidates to 11 years—and for the Royal Masonic Institution for Girls May Irene Mackay. I may add that I have ascertained that the names of the deceased fathers of these children were in the Medical Register of 1895.

A PROPOSED BACTERIOLOGICAL LABORATORY FOR PLYMOUTH.

A MOVEMENT has been set on foot having for its object the establishment of a bacteriological laboratory for Plymouth. At a recent meeting of the Plymouth borough council a petition on the subject signed by a large number of the medical men of the district was presented asking the council to establish a "municipal laboratory in which certain prevalent and infectious diseases could be recognised by modern bacteriological methods of examination."

WHY APPENDICITIS?

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent's letter in THE LANCET of March 28th, p. 936, asking me why I called the case described by me in THE LANCET of March 21st, p. 797, one of appendicitis my reasons are as follows: (1) the fæcal smell of the pus, showing it to be connected with the bowel; and (2) the adhesions which had formed were in the vicinity of the appendix. Elsewhere there were flakes of lymph but no adhesions, showing that except close to the appendix the peritonitis had not existed long enough for them to be formed.

I am, Sirs, yours faithfully,
Royal Infirmary, Windsor, March 30th, 1903. F. E. WOOD.

DOES SPITTING ON THE GROUND SPREAD TUBERCULOSIS?

To the Editors of THE LANCET.

SIRS,—We see notices up and down, which are an eyesore, requesting people not to spit about, and such notices should be unnecessary, as it is undoubtedly a dirty habit; but what I wish to point out is that such spitting decreases the danger of infection rather than increases it, for the following reason:—Suppose a person suffering from phthisis spits in the middle of the road, what happens?—the sputum dries and the bacilli are scattered about and cannot possibly arrive in sufficient numbers anywhere so as to cause infection; on the other hand, he spits into a handkerchief time after time, and at the end of the week he sends a dozen or so handkerchiefs loaded with tubercle bacilli to a laundry; surely these are a great source of danger? Someone says, let him spit into a disinfectant in a bottle. Now, is it likely anyone would care to take out a bottle in public and spit into it. Of course not, if he did so in a railway carriage everyone would get out at the next station. He might of course put his handkerchief in a disinfectant when he got home (if he happened to know he had phthisis), but in the meantime his pockets get full of bacilli and every time he pulls out his handkerchief a cloud of these are disseminated around into his—it may be—badly ventilated office, or wherever he happens to be.

I am, Sirs, yours faithfully,
Leytonstone, N.E., March 23rd, 1903. ARTHUR TODD-WHITE.

THE END OF A DISPUTE.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 28th, p. 932, the action between Mr. E. C. A. Baines and myself is described as one in regard to slander only, ignoring the (professionally) far more important factor of an alleged breach of contract with regard to which Mr. Baines has equally withdrawn every allegation.

I am, Sirs, yours faithfully,
W. LONGWORTH WAINWRIGHT.
Henley-on-Thames, March 30th, 1903.

LORD KITCHENER'S HOME-COMING.

THE proprietors of Bovril, Limited, have made an arrangement whereby the purchasers of bovril will be able to obtain an artist's proof of the picture by Mr. William Hatherell, R.I., entitled "Lord Kitchener's Home-Coming," at no more trouble to themselves than is required for the collection and forwarding of coupons of the aggregate value of one guinea. Until June 30th every bottle of bovril will bear a coupon varying in value in proportion to the size of the bottle; a 2-ounce bottle will bear, for example, a coupon for 1*s*. and a 16-ounce bottle a coupon for 5*s*. These coupons to the necessary value must be sent to the Bovril Company, when the picture will be forwarded. The proprietors of bovril have sent us a signed artist's proof of the picture which is an exceedingly well-executed reproduction of Mr. Hatherell's fine painting.

HEALTH RESORTS DURING SPRING.

To the Editors of THE LANCET.

SIRS,—Will you allow me to ask any of your readers what in their opinion is the best place (health resort and midland counties preferred) where the east wind during the spring can be avoided? I am a sufferer from insomnia and asthma chiefly and prefer a high and dry situation, protection from the east wind being the chief desideratum. Of course, the best place is where out-door exercise on level ground is obtainable, but I fear the requirements are difficult of attainment. Leamington is the only place which I can think of and I fear that one being relaxing. Shady walks are a *sine quâ non*, as the sun is my great enemy.

I am, Sirs, yours faithfully,
April 1st, 1903. MEDICUS.

◆

Anxious One.—We are unable to print our correspondent's question, but if her medical man likes to put the difficulties of the case before our readers he may obtain suggestions for treatment.

Etiquette.—When the appointment is vacant there is no reason in all the circumstances mentioned why our correspondent should not apply for it.

A. L. B. is thanked for his communication. The similarity had been pointed out to us.

ERRATUM.—In THE LANCET of March 21st, p. 837, appeared a letter from Mr. Hugh E. Hoare on "Cottage Homes for Pauper Children" in line 10 of which the words "barrack room" should have been *barrack school.*

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

EDITORIAL NOTICES.

is most important that communications relating to the orial business of THE LANCET should be addressed usively "TO THE EDITORS," and not in any case to any leman who may be supposed to be connected with the orial staff. It is urgently necessary that attention be n to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1902, which was completed with the issue of Dec. 27th, and the Title-page to the Volume, were given in THE LANCET of Jan. 3rd.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1902 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

The Hunterian Lecture

ON

THE SYMPTOMS AND DIAGNOSIS OF STONE IN THE KIDNEY.

Delivered before the Hunterian Society on Feb 25th, 1903,

By R CLEMENT LUCAS, M B, B S Lond, F R C S Eng,

SENIOR SURGEON TO AND LECTURER ON SURGERY AT, GUY'S HOSPITAL, CONSULTING SURGEON TO THE EVELINA HOSPITAL FOR SICK CHILDREN

[After thanking the President and council for the honour conferred upon him by selecting him to deliver the lecture Mr Clement Lucas proceeded as follows —]

Looking through the records of past lectures I find that the lecturer has generally chosen a subject in which he could claim some exceptional experience and he has then proceeded to give the results of his personal observations rather than a collection of the views of others This is very characteristic of John Hunter's own method, and endeavouring to act in this spirit I have chosen for my subject "The Symptoms and Diagnosis of Stone in the Kidney"

I will first relate the history of a typical case and then proceed to analyse the symptoms in detail, showing how greatly they vary in different instances and how important it is to weigh their relative value before arriving at a conclusion

A young man, 24 years of age, consulted me three years ago on account of attacks of pain and hæmaturia His parents were living and healthy and he had five brothers and sisters, also healthy and well He was brought up on a chalk subsoil Five years previously he injured his side at football but his symptoms did not commence till a year later He then first suffered from a severe attack of pain in his left loin running through to the front and into his groin and testis This lasted for three or four hours and then he got quite well. He did not notice any stone or gravel in his urine but it often had brick red deposits The second attack occurred about a year later and passed off in a similar way Since then he had had frequently recurring attacks, always on the same side He first noticed blood in his urine one and a half years previously after a game of tennis This had occurred at frequent intervals since especially after exercise Once or twice the hæmorrhage had followed the attacks of colic In the intervals he felt well but was afraid to exert himself in any way The attacks of colic always caused nausea and had once or twice induced vomiting His urine when examined by the microscope showed numerous crystals of uric acid and litholes but no blood or pus Acting on these symptoms I cut down on his kidney and removed a uric acid calculus weighing *48 grains*

I will now proceed to speak of the symptoms in detail

I Pain

Pain perhaps more often than any other symptom first draws attention to the existence of stone in the kidney Yet important as this symptom is its inconstancy, radiation reflection and tendency to cause sympathetic aching of the other organ, diminish its trustworthiness so that pain when considered alone is apt to lead rather to uncertain and incorrect conjecture than to exact diagnosis It will be necessary *to analyse very carefully* this symptom *before* drawing any conclusion from it

1 In the first place it should be noted that in a certain number of cases *pain may be altogether absent* Post-mortem records abound in cases in which patients dying from diseases of other organs were found to have calculi often of large size, imbedded in the kidneys which gave rise to no symptoms during life I will only allude to one brought before the Hunterian Society years ago, that of a man who died from a sarcoma of the heart who had an enormous calculus in each kidney that had given no evidence of their presence during the man's lifetime

To what can the extreme variability of the symptom of pain be attributed? Why is it that in one case a renal calculus may excite so little discomfort that the patient is unconscious of its presence whereas in another agony of the most distressing and excruciating character is caused by a stone in the kidney? I think that I shall be able to show that this variability of the symptom of pain depends upon two factors (1) the position of the stone and (2) its mobility or fixation

Taking the position of the stone first it can be shown that the secreting structure of the kidney possesses little sensibility and a stone firmly fixed in the fleshy part of the organ may excite little or no sense of pain I once had an opportunity of directly testing the sensibility of the secreting part of the kidney in a man whose kidney had been exposed by a wound in the loin He appeared to be quite indifferent to punctures of the fleshy part of the organ I have also frequently tested it during operations when the patient has been but *partly* under an *anæsthetic* *Provided that the* organ be not moved so as to drag on its nerves puncture of the cortical and medullary portions causes no evidence of pain Another way in which the sensibility of the solid parts of the kidney may be tested is when a very moveable kidney is met with in a very lax abdomen In these circumstances it is often easy to grasp the kidney in the hand and to compress it, when a sensation somewhat similar to that caused by squeezing a testis or an ovary is produced, but much less severe in character It must be remembered that the kidney lies behind the intestines and that in compressing it in this way the intestines are squeezed at the same time and pressure upon them may account for part of the pain induced The pelvis of the kidney and its branches are, however, acutely sensitive, and, as in the case of the urinary bladder, the most sensitive part is that immediately around the outlet A moveable stone impinging upon this point excites the most excruciating agony Very large branched stones may be met with occupying the pelvis and calices of the kidney which being firmly fixed have caused only aching pains, quite distinct from the agony of renal colic and it may be stated as a general axiom that the mobility of the stone is the chief factor in bringing about attacks of renal colic

2 The next point to be considered is that *pain to be of service in the diagnosis of renal calculus must be unilateral* It usually is so, but cases are met with in which with a stone imbedded in one kidney, the patient complains only of general backache or pain in the loin and is quite unable to distinguish one loin as being more painful than the other Such a case came under my notice three years ago The patient was 32 years of age and a very heavy drinker Six or seven years before he had suffered for some time from albuminuria following an attack of diphtheria 18 months before I saw him he suffered from backache and passed blood in his urine and was treated for congestion of the kidneys. He suffered also from headache Occasionally since he had noticed a little blood in his urine When I saw him in January, 1900 his urine was turbid when passed and contained an excess of phosphates, some mucus and a considerable quantity of albumin When questioned as to pain he put his hand on his spine in the hollow of his back and he was quite unable to distinguish the pain as greater on one side than the other This was just the case in which had the pain been unilateral the symptom would have been of value since he had shown signs indicating degenerative changes in his kidneys and his habits were such as to predispose to these pathological changes Yet it was not till three months later, though his attention was constantly drawn to the point that he would admit the pain to be greater on the left side than on the right and I then removed an enormous stone with five large processes from the pelvis of his left kidney a stone which I think must have been years growing to the size it had attained when I removed it.

3 *The character of the pain varies greatly in different cases* An aching gnawing pain extending from the loin through to the front on a lower level is what is most commonly complained of It begins at the lower edge of the last rib behind in the angle between this and the spine and is felt in front below the level of the umbilicus along the edge of the rectus muscle The explanation generally given of this pain is that it commences in the renal plexus and extends downwards along the ureter Whilst not denying this source of pain I think that the particular symptom is more correctly explained by reflection along the last dorsal nerve, which may be regarded as a protecting nerve to the kidney The almost certain relief of pain which follows on

R

exploration with division of this nerve, where a stone exists but has been undiscovered at the operation, supports the explanation which I have suggested. Transference along the ilio-hypogastric or ilio-inguinal nerve would bring the anterior pain lower.

4. *Attacks of renal colic*, which are to be observed in their most acute form during the passage of a small calculus through the ureter, frequently occur at intervals as the result of a stone lodged in the kidney. As I have before explained, such attacks are most likely to occur as the result of a moveable stone dropping like a ball-valve over the outlet of the pelvis. Not only is the most sensitive part of the organ then struck but the ball-valve action obstructs the passage of urine and causes backward distension and pressure upon the secreting structure of the kidney. The sudden blocking up of half the urinary secretion tends to a uræmic condition which favours vomiting, a symptom which is also encouraged by the connexion of the pneumogastric nerve with the renal plexus.

It must not be concluded that attacks of renal colic only occur from a loose stone in the pelvis of the kidney. They occur in a modified form when a stone lies loose in a dilated cavity. Calculi by blocking the outflow of urine may cause hydronephrotic cavities behind them in any part of the kidney; for it is one of the most curious and interesting facts in physiology that the secreting force of the kidney is sufficiently strong to destroy the secreting structure by the backward pressure of the fluid it has secreted. A stone becoming loose in one of these cavities and being driven into the narrow sensitive neck of the calyx through which it cannot pass gives rise to attacks of renal colic though not so severe as those in which a stone drops on the outlet of the pelvis. Attacks of colic dependent on stone may also be caused by hæmorrhage when it occurs with such rapidity as to coagulate within the kidney. The passage of such clots may excite severe pain.

Nephritic colic in its most characteristic form gives rise to the most intense distress, commencing in the loin and extending downwards to the groin and testis. The patient doubles himself up and groans with agony or rolls about tossing the bed-clothes and twisting over and over in his endeavour to gain a position of rest. Nausea, retching, and vomiting occur, followed by fainting and collapse. Beads of perspiration stand out on his forehead and the surface of his body is cold and moist. Retraction of the testis towards the inguinal canal may be noticed, consequent on spasm excited in the cremaster muscle, but it is by no means a constant symptom and occurs much more frequently in boys than in adults. Frequent micturition and pain reflected to the end of the penis not infrequently accompany the attack, but these symptoms are much more marked when the stone is in the ureter than when it is in the pelvis of the kidney.

5. *Transference, radiation, or reflection.*—Under these terms are described pains removed altogether from the site of the original exciting cause, though frequently associated with pain in that situation. The intimate connexions of the renal plexus with surrounding nerves permit of pain being reflected to the ends of various spinal nerves. The upper lumbar nerves are those along which these impressions more frequently travel, but instances are on record of a renal calculus exciting pains in the thigh, knee, hip, ankle, and foot, along branches of the anterior crural and great sciatic nerves of the same side. Thus in vol. xxii. of the Transactions of the Clinical Society, Dr. Steavenson and Mr. Butler-Smythe relate a case of renal calculus which owing to pains in the sole of the foot, hip, knee, and ankle, had been treated for sciatica until a renal tumour was discovered. The most familiar and striking instance of transference of pain is when pain is so concentrated in the testis as completely to divert attention from the kidney. Six years ago a youth was referred to me whose left testis had been kept carefully strapped for some weeks owing to pain and, it was thought, some enlargement of the epididymis. Having removed the strapping I found little abnormal about the organ, but I was attracted by the patient saying that at times the pain was so severe that he had to squeeze the testis in his hand to relieve the agony. He also admitted that the pain went up to his back and was brought on by heavy work. He had never suffered from gonorrhœa or had any injury to the testis. Following out my inquiries I came to the conclusion that he was suffering from a calculus in his left kidney, which I afterwards verified by operation, and by removing the stone I completely relieved him of his symptoms. In relating this case I wish at once to admit that I was assisted in the diagnosis by my recollection of a case related in vol. xv. of the Transactions of the Clinical Society in which the pain being concentrated in one testis Mr. A. Willett made a diagnosis of stone in the kidney that was afterwards proved to be correct by Mr. H. T. Butlin.

6. *Increased pain at night* is sometimes complained of but is by no means a constant accompaniment of renal calculus. In my experience it is only met with in association with very large or multiple stones. The explanations that have been offered of this occurrence are not to my mind satisfactory. One is that it is due to the passage of flatus in the colon over the pelvis of the kidney containing a stone, and another is that it is due to the concentration of urine and deposit of crystals at this time. A more reasonable hypothesis would be that, as the heart beats with less force at this time and so gives less impetus to the blood in distant channels, there is a tendency to congestion of the central organs and the congested tissues would be brought with their nerves into more forcible contact with the unyielding stone. If, however, as I have stated, this symptom is only met with in the cases of very large or multiple stones a simpler mechanical explanation is probably the correct one. In the recumbent position the heavy weight of the calculous kidney would press injuriously on the upper nerves of the lumbar plexus and in turning over to the opposite side its weight would tend to displace it, to drag on the nerves about its pedicle, and to press on the colon. I have frequently observed that patients with stone in one kidney are unable to sleep on, or even to turn on to, the opposite side without pain.

7. *Tenderness over the kidney* is a sign of value, especially when the stone is large or angular. It is best determined by placing the patient in the recumbent position, telling him to draw up his legs and to take deep inspirations. Bimanual manipulation is then employed, the fingers of one hand being deeply pressed into the loin in the angle between the last rib and the erector spinæ, whilst the other hand is pressed in beneath the ribs in front. During a deep inspiration the kidney can be caught between the hands and a sudden lancinating pain is sometimes caused if a stone be present, sufficiently acute to cause the patient to cry out. Should blood appear in the urine after such manipulation this would confirm the diagnosis. Sudden percussion of the loin, as suggested by Mr. Jordan Lloyd, I have not found to be of value. It is apt to frighten the patient and to deceive the surgeon.

8. *The pain is increased by jolting exercise.*—This is a valuable sign. A ride on an omnibus, in a light cart, or on certain of our railway lines may help materially to clear up a diagnosis. This sign assisted me greatly in arriving at a correct diagnosis in a somewhat remarkable case that I saw in the summer of 1893. A solicitor had been suffering for some years from a pain in one loin and pyuria. He had had the benefit of the advice of two or three of the most distinguished physicians and surgeons in London who had arrived at the conclusion that he was suffering from a tuberculous kidney. As the result of their advice he had sold his practice and was about to proceed to the high altitudes of California to combat the supposed tuberculous infection. Dr. G. Wilks advised him to consult me before taking this step. He accordingly journeyed to London one morning by a railway at that time not specially distinguished for smooth travelling and when he arrived at my house he was suffering severe pain as a consequence of the journey. His urine passed at my house besides containing a large quantity of pus was tinged with blood which was an unusual occurrence that I also attributed to the journey. The urine was sent to the late Dr. J. W. Washbourn for bacteriological examination and he failed to discover any sign of bacillus, either by staining and microscopic examination or by the injection of a guinea-pig. The patient's family history was free from any taint of consumption and pointed rather to longevity and gout. Upon this evidence I advised that he should have his kidney explored for stone. I had arranged to do this when I was seized with typhoid fever, so that the operation was performed by Sir Victor Horsley who removed a large stone and completely relieved the patient of his symptoms.

9. *The pain is said to vary with the composition of the calculus.*—According to Prout and Dickinson oxalate of lime causes the most acute pain with sharp radiating pains in various directions; uric acid calculus causes the least pain; whilst phosphatic stones give rise to a constant severe pain.

I do not think any great reliance can be placed upon these statements, as the amount and variety of pain depend much more upon the position and mobility of the stone than on its composition Phosphatic stones, however, being associated with a chronic pyelitis do, in my experience, give rise to a more constant ache than the other varieties

10 *The stamping test* —I have of late invented a new test which sometimes gives the most remarkable results The patient supports himself by resting one hand on some firm object, then is told to flex the thigh on the suspected side as high as possible The psoas muscle being thus strongly flexed, by its contracted belly presses the kidney forwards and outwards Next the patient brings the limb suddenly down, stamping the heel firmly on the ground The kidney in this way suddenly loses its muscular support and is caught, as it were, unawares, whilst the jar carried through the pelvis and spine is communicated to it A sudden acute pain is commonly caused by this manœuvre when a calculus is present In one case in which I employed this test it answered only too well, for the patient was immediately seized with acute renal colic which necessitated his being put to bed, where he lay for some hours in great agony It was evident that a stone had been displaced from a calyx and had fallen over the outlet of the pelvis whence it was removed by operation some days later

II HÆMATURIA

This symptom is associated with so many affections of the kidneys that taken by itself it is of little value in the diagnosis of calculus As a rule it follows the usual course of renal hæmorrhage, being equally mixed with the urine when passed and not interspersed with clots It may in certain cases be so slight as to give just a faint smoky tint or a "thin red line" at the high-water mark of the urine left in a chamber, whilst in others it may stain the urine a deep purple red colour or give it the dark opaque, muddy appearance of porter In rare cases it coagulates in the pelvis and ureter, giving rise to very characteristic clots These pelvic clots are somewhat triangular in outline and represent moulds of the pelvis and they sometimes carry, what is very characteristic, a long and very narrow tail moulded in the ureter More often these narrow mouse tail clots are separately detached and they may be six or eight inches in length, generally terminating in a bleached fibrinous end where the corpuscles have been washed out by the urine They are so narrow that they cannot be mistaken for clots moulded in the urethra In every case where clots are noticed they should be floated out in a basin of water and the water renewed time after time after pouring off the supernatant liquid till the clots lie in clear water In one case in which clotting in the pelvis was frequent I noticed a cavity in the majority of the clots passed, which was so constant in size and shape that I correctly diagnosed that the clot took the mould of a stone It must not be forgotten, however that a hollow in a clot may be caused by the projection of the papillary end of a pyramid or be moulded on a vascular papilloma of the pelvis

1 *Hæmaturia occasionally occurs in persons a little out of health without being the expression of any serious pathological condition* —"Some persons bleed from the nose, others from the kidney," was a favourite dictum of the late Sir William Gull, A little increase of hæmic pressure and feebly resisting capillaries might account for such transient disturbance in the condition of the urine, unaccompanied by other symptoms Among the more serious conditions giving rise to renal hæmaturia may be mentioned oxaluria, excess of uric acid, acute Bright's disease, granular contracted kidney, tuberculous pyelitis, papillomata of the pelvis, and new growths attacking the secreting structure

2 *The symptom of hæmaturia may be entirely absent* throughout the course of the case I could quote case after case in which this symptom had never been noticed, and curiously enough in such cases the stone is often proved to be both large and irregular But I will only allude to one brought before this society in the year 1896 by Dr Arthur T Davies The patient was a man, aged 23 years, who for two years had been liable to attacks of renal colic. There was a history of his father having passed a stone. "He had not noticed any alteration in the colour of his urine" A calculus composed of oxalate of lime and uric acid was extracted by Mr S Paget.

3 *Hæmaturia may be the only symptom* —The hæmaturia may be profuse and yet quite unassociated with pain. Such was the case in a patient who came under my care in Job Ward, Guy's Hospital, in 1899 He was 64 years of age He was thin and pale and had lost one and a half stones in weight during the previous 12 months His symptoms commenced ten months before admission when he first noticed blood in his urine This was at first observed only in the morning, but latterly had been continuously present He had suffered no pain in either loin or pain on micturition Some frequency of micturition had been experienced, chiefly at night, but it was not marked He did not strain to pass urine and there was no dribbling The blood was always evenly mixed with the urine and there were no clots It was of the colour of porter I discovered that the right kidney was enlarged, smooth, and painless He was repeatedly skiagraphed with negative results The urine contained no pus and he passed on an average 250 grains of urea in 24 hours Taking the age, pallor, wasting, painless tumour, and profuse hæmaturia, together with the negative result of the skiagraph, into consideration I came to the conclusion that the patient was suffering from cancer of the kidney, but I recommended an exploration and was prepared to remove the kidney if necessary or advisable On Nov 28th, 1899, I exposed the kidney by an incision through the loin and found it in a hæmato nephrotic state and filled with stones I drew off the liquid blood by means of a cannula and then excised the whole organ It contained six oxalate of lime stones, the largest of which weighed 200 grains The patient was discharged cured on Jan 5th, 1900 This case shows that profuse hæmaturia may be the only symptom present when the kidney is being destroyed by multiple calculi, for the patient was quite unconscious of any tumour in his abdomen until I discovered the enlarged kidney and was quite free from pain

4 *Hæmaturia due to calculus is almost invariably excited or increased by severe exercise* —This becomes more evident and characteristic if the patient is employed in a sedentary occupation Thus, a patient from whom I removed a calculus two years ago was in the habit of sitting in his office six days in the week and of taking a long country walk of many miles on Sunday On Monday morning after these walks he noticed that hæmaturia was regularly present. Riding in omnibuses or motor cars, taking long railway journeys, and such like, are extremely liable to excite hæmaturia if a renal calculus be present

5 *Hæmaturia following an attack of renal colic is very characteristic of calculus*, especially if the colic follow severe exercise It is, however, by no means regularly present after, or in association with, colic Colic frequently occurs without hæmaturia and hæmaturia without colic

6 *Hæmaturia dependent on calculus quickly subsides with rest in the horizontal position* —Being commonly caused by the wounding of vessels through the movement of a calculus within the kidney, or by the movement of the kidney itself when containing a stone, rest in bed contributes in this more than in other conditions to the rapid subsidence of the hæmorrhage

7 *Calculous hæmaturia may be so great as to cause death*, in such rare cases as those in which ulceration takes place into a large branch of the artery or vein It might have caused death in the old man whose case I related under paragraph 3 had not nephrectomy been performed, and it actually caused death in the case reported by Dr Steavenson before alluded to, on the seventh day after nephrectomy, from the ulceration caused by a stone that had been left at the operation extending into a large branch of the renal artery As a rule, the narrow outlet prevents this fatal accident Coagulation takes place in the ureter and backward pressure stays the hæmorrhage at the expense of the secreting structure

III —FREQUENT MICTURITION.

Frequent micturition may be met with in association with renal calculus but it is by no means constantly present, and it would appear to be due more often to conditions secondary to the stone than to the reflex effect of the calculus itself Thus if the stone excite pelvic mucus in quantity, hæmaturia, or pyuria, any one of these conditions may be the immediate cause of the irritable bladder Of these, pus in the urine is by far the most frequent concomitant of irritable bladder Urine loaded with deposits of phosphates or lithates may also be found in association with renal calculus and these deposits rather than the presence of the stone are the probable cause of the frequent micturition.

1. *Frequency in micturition may even give place to extreme tolerance*, as in a patient from whose left kidney I removed seven calculi in November, 1900. This patient, to whom I shall again allude in connexion with the diagnosis of multiple calculi, stated that owing to the pain of straining to pass urine which was severely felt in her left side she was in the habit of only passing it once in the 24 hours. Her urine was clear and free from blood and pus.

2. *Extreme irritability of the bladder and painful micturition felt in the perineum and at the end of the penis may be caused by a stone impacted in the ureter.*—So marked were these symptoms in a case published by my colleague, Mr. F. J. Steward, in vol. xxxiv. of the Transactions of the Clinical Society, that he was induced to open the bladder and was then able to feel the stone through the bladder wall lying in the ureter. A stone was lodged in the ureter, I have little doubt, in the case of a man who was under my care in Guy's Hospital last year suffering from similar symptoms. This man had suffered from repeated attacks of right renal colic and hæmaturia, but vesical irritability, with reflected pains along the perineum and penis, were also marked symptoms. The Roentgen rays failed to demonstrate the presence of a stone, but the pains were so clearly traceable to the right kidney that I explored it through the loin with a negative result. As so frequently happens, the operation entirely relieved him of his symptoms and he left the hospital quite free from pain. He returned three months later with a recurrence of the symptoms, and whilst I was contemplating an operation on his ureter he voided a small calculus with his urine and was thus completely relieved.

From these observations it will be deduced that frequent micturition, occurring independently of any abnormal urinary deposit and due to reflex irritation, bears a closer relation to the ureter than to the kidney, and when it is associated with renal calculus the stone will probably be found in the dilated upper part of the ureter or pelvis of the kidney and not imbedded in the secreting structure.

3. *Frequent micturition, sudden uncontrollable desire to pass urine, and incontinence* may be met with in children from the presence of a stone in the kidney. I have also seen reflex distension of the bladder brought about by the same cause acting through a different circle of nervous influence.

IV.—Retraction of the Testis.

Retraction of the testis may be occasionally noticed during an attack of pain in adults, but it is a much more obvious and important sign in children under the age of puberty. I have seen the testis drawn completely up into the inguinal canal in a boy during an attack of pain. More often it stops at the external abdominal ring. After puberty, as the testis increases in weight and the cremaster grows feebler with age the retraction of the testis becomes less obvious and consequently its importance as a symptom of less value.

V.—The Passage of Small Calculi or Gravel on Previous Occasions.

The passage of small calculi or gravel on previous occasions is perhaps the most important information that can be obtained from the former history of the patient. With such a record occurring in a patient the subject of hæmaturia and renal pain the presumption of a calculus retained in the kidney would be a sound and almost certain deduction. Such a history was obtained in the case of a woman from whose left kidney I removed seven faceted calculi in the year 1900. She had suffered from unilateral pain in the loin for five years and had passed at intervals two calculi as large as peas and several smaller ones. A history of having on two occasions passed a small calculus was present in another case that I operated upon last year.

VI.—The Grating of Multiple Calculi.

This is the only definite indication that we possess of the presence of multiple calculi, and for it to be obtained it is necessary that two at least shall be in contact. I have met with it on three occasions. The first occasion on which I had an opportunity of feeling the grating of stones in a kidney was in June, 1885, in the case of a patient who had suffered for 17 years from hæmaturia at intervals and who had a moveable right kidney that could readily be grasped and the stones contained within it grated one on another. This kidney when removed was a mere shell containing masses of stone that weighed 21 ounces. The second case in which I had an opportunity of testing this symptom was in a boy, aged 15 years, who was under the care of Dr. J. F. Goodhart in 1888. He referred his symptoms to the left side and when the neighbourhood of the last rib was pressed upon a grating sensation could be very distinctly felt. So evident was this grating that some were inclined to think that he might have fractured his last rib. Subsequently it was shown that he had numerous calculi in both kidneys, the left being a capsule filled with stones. The third case in which this symptom was noticed came under my care in Martha Ward on Nov. 5th, 1900. The patient was a married woman, aged 29 years. As I have already alluded to her case as presenting certain anomalies I will give it now in more detail. The patient, who gave a sound family history, had given birth to two children, aged five and three and a half years respectively. Pain commenced in her left loin five years before and whilst under treatment she passed a stone of the size of a pea and was relieved. The pain returned one and a half years later and then, whilst again under treatment, she passed one large stone and several smaller ones and was relieved. But the pain in the left side recurred and had been increasing very much during the last three weeks. The pain became acute when walking, but subsided on lying down. She had never noticed any blood or deposit in her urine. She had no difficulty in passing urine till three weeks previously, when she had to strain, and the pain in her left side when straining became so severe that she only passed her urine once in the 24 hours. She had shooting pains which were confined to the left side and the pain was most acute before passing urine. On manipulating her left kidney in the bi-manual method a definite grating could be felt. The urine was of clear straw colour with a specific gravity of 1024 and contained neither blood nor pus. The skiagram showed a dark shadow two inches by one and a half inches in diameter. I operated on Nov. 20th and removed seven faceted stones from the pelvis of the kidney. She was discharged cured on Dec. 14th, 1900.

VII.—Total Suppression of Urine.

When symptoms of total suppression of urine set in with intense pain in one loin shooting through to the front and down to the groin, constant futile attempts to pass urine, vomiting, headache, giddiness, and restlessness, the surgeon should at once take into consideration the probability of those symptoms being caused by a calculus obstructing the outlet of the only remaining kidney. I had for some years been advocating operation for the relief of such symptoms, as case after case was published ending fatally, before I had the opportunity of putting my views to a practical test. This happened at the end of October, 1885, when the patient already alluded to as having one kidney removed for immense calculi that could be grated together during life was seized with the symptoms of total suppression of urine. Through the promptitude of Mr. F. D. Atkins of Sutton, Surrey, I was able to get the patient brought up to London and on the fifth day of total suppression I cut down on the remaining kidney and removed a conical stone that was blocking the outlet of the pelvis, and so saved her life. The case was published in full, five years later, in the volume of the Transactions of the Royal Medical and Chirurgical Society for 1891, when she was still living. I am now, by the courtesy of Mr. E. Morgan Hearnden, who is a partner with Mr. Atkins, able to add a further interesting note of this patient. He writes on Feb. 6th, 1903: "I called to-day on Mrs. —— and found her in perfect health; in fact, she has never been ill since you operated on her." So I am in a position to state that 17 years and four months after an operation on a single kidney for total suppression of urine the patient is not only alive but in the enjoyment of good health.

VIII.—Shadow Photograph by the X Rays.

The demonstration of the presence of a stone in the kidney by means of the Roentgen rays has added much precision to the diagnosis in a considerable number of cases and with increasing experience the number of failures will probably be greatly lessened. At present, however, the shadow photograph, when negative, cannot be implicitly relied upon. When speaking of hæmaturia without pain I related the case of a man, aged 64 years, under my care in 1899, who was repeatedly skiagraphed with a negative result, so that I was led into error in diagnosing his case as one of cancer. Yet I found on exploration that this man's kidney contained six calculi which had practically destroyed the secreting structure Whether the blood with which the kidney was filled obscured the view I am unable to say, but certain it is that with ample opportunities and repeated attempts the Roentgen rays failed completely, though the calculi were oxalate of lime The kidney moves up and down in respiration to the extent of an inch or one and a half inches This fact and its distance from the surface are the causes, no doubt of the exaggeration in size so often shown in a skiagram In 1900 I operated for a second time on a boy whose kidney I had explored unsuccessfully *three years before After the exploration the symptoms* entirely subsided but returning led him again to seek advice three years later This time the Roentgen rays demonstrated a stone said to be one inch by one and a half inches, but when after a prolonged search I discovered it high up in a cavity communicating by a small aperture with the pelvis it proved to be only of about the size of the tip of the little finger The next case explored by the same radiographer for me in 1900 was that of a patient who had pain, hæmaturia and phosphatic urine The photograph taken was said to be a failure, but a stone was thought to be demonstrated on the screen and stated approximately to be from half an inch to an inch in diameter This proved to be an enormous phosphatic stone with five large branches measuring three and a half inches by two and a half Whether the radiographer was afraid to state correctly the enormous shadow seen or whether he photographed a small nucleus of a different chemical composition I am unable to say, but it shows that the determination of size by the Roentgen rays may be very misleading Better results no doubt would be obtained if the patients were instructed to hold their breath and so to fix the diaphragm during the time—only some 20 seconds—required for a skiagraph Of the three principal forms calculi oxalate of lime gives the darkest shadow, phosphatic calculi come next in point of clearness, whilst the uric acid are the least defined

Mr E W H Shenton radiographer to Guy's Hospital, states in a paper published in the Guy's Hospital Reports of last year that there had been 28 cases in which calculi demonstrated by the x rays had been found by the surgeon, eight cases in which the surgeon found calculi which the x rays had failed to show, and two cases in which the x rays had discovered calculi which the surgeon had failed to find by operation

IX.—Family History

I have placed this last because, though of some assistance, it is often very misleading For instance, in the case of the patient who had stones in both kidneys and had never shown the slightest tendency to tubercle the family history pointed strongly in that direction, for her mother, two sisters, and one brother died from consumption Her father had gout and died from congestion of the lungs so that we must presume, if heredity in her case had any influence, that she followed closely her father s line A history of gout or of the passage of gravel or calculi by some other members of the family especially if the person lives in a district where the water is hard, might give presumptive evidence in favour of stone On the other hand if the patient be of a delicate build, with a strong tuberculous history, and especially if, in addition, there be any evidence of former tuberculous infection about the glands in the neck, lupus of the skin, or ankylosis of a joint from a chronic inflammation in childhood, these indications of a tuberculous tendency must be given their due weight in considering the diagnosis.

X —Various Conditions liable to be Mistaken for Renal Calculus

I have gone so into detail in analysing the symptoms characteristic of stone in the kidney that I must condense my remarks as much as possible in speaking of the various conditions liable to be mistaken for renal calculus

1 *Tuberculous disease of the kidney* is perhaps more often mistaken for renal calculus than any other affection Hæmaturia, lumbar and reflected pains pyuria and frequent micturition may be present in either case Yet there are many distinguishing points

(*a*) The *hæmaturia* of tuberculous disease may be a striking feature in the early stages but it is then accompanied by little if any pain, whereas the hæmaturia of calculus is usually preceded by pain and markedly excited by exercise In the later stages of tuberculous disease the hæmaturia is often very slight and sometimes it is entirely absent

(*b*) The *pyuria* of tuberculous pyelitis is an early symptom and often *precedes for months any noticeable lumbar pain.* Thus a woman aged 43 years, who was under my care in September, 1900, had noticed the deposit of pus in her urine for three months before she suffered from pain in her right loin The pyuria of calculus is a late symptom and often entirely absent.

(*c*) The *pain* of tuberculous disease is a continuous dull aching pain not liable to the intense exacerbations or to the wide radiations of calculus It increases as the disease extends and the kidney becomes dilated into suppurating cavities *Taking these two symptoms* pain and pyuria together, I have for years formulated as an axiom for students that ' pain in excess of pus indicates stone, pus in excess of pain tuberculous pyelitis "

(*d*) Slight attacks of chilliness not amounting to rigors followed by a rise in temperature are frequent in the course of tuberculous kidney and the temperature at night is often above normal. Renal calculus seldom causes increased temperature

(*e*) Examination of the deposit of pus by staining and the microscope will occasionally discover the presence of the tubercle bacillus but it too often fails to be trustworthy as a negative test Dr H S French, now medical registrar at Guy s Hospital, when my dresser, after repeated examinations in a case under my care at last discovered a single bacillus, but this was quite characteristic and the diagnosis strengthened by this discovery was proved to be correct. The injection of guinea pig with the deposit is a more certain test. The late Dr Washbourn thus proved a case of tuberculous kidney for me when staining and the microscope had failed

(*f*, [illegible] is tl [illegible] roof [illegible] bladder I first discovered this in a case under the care of Dr (now Sir Samuel) Wilks in Clinical Ward in 1883 and in June 1884 I was able to demonstrate it to Dr (now Sir William) Broadbent in a case sent up by Dr Clarke of Huddersfield for joint consultation I have constantly taught the importance of this symptom during the last 20 years The ureter painful and thickened could be distinctly felt in a patient now in Martha Ward under my care whose tuburculous kidney I excised recently for a sinus following drainage of the kidney Another consequence of this condition is frequently met with It renders sexual connexion so painful as to be intolerable This was stated to be the case by the woman I have before alluded to as having pus in the urine before pain was established in the loin The same thickening of the ureter can occasionally be demonstrated by rectal examination in men

2 *Moveable kidneys* give rise to attacks of colic accompanied by nausea and vomiting similar to what are observed in the course of renal calculus and the condition is always one improved by rest , but the urine in these cases is almost invariably normal as regards its constituents though liable to vary greatly in quantity at times if the mobility has given rise to intermittent hydronephrosis The discovery of the abnormal mobility of the kidney helps to clear the diagnosis The aching kidneys described by Dr Matthews Duncan were for the most part kidneys unduly mobile, a condition which at the time when he wrote was but little understood

3 *Lithiasis and oxaluria* may occasion hæmaturia and severe pain in the loin, but the pain is not unilateral and the condition is one that can as a rule, be cured by freely flushing the kidneys by drinking large quantities of distilled water

4 *Acute Bright s disease and chronic granular or gouty kidney* may give rise to pain in the loin and hæmaturia but the persistence of the albumin when blood is absent the low specific gravity of the urine, and the usual indications of arterio-capillary fibrosis in the chronic disease will serve to point out the nature of the malady

5 *Villous growth in the pelvis of the kidney* is a rare affection which may give rise to very free hæmorrhage without pain or appreciable tumour Clots may indicate the source of the hæmorrhage and portions of growth washed away may show the nature of the disease

6 *Malignant growths of the kidney* first indicate their presence by free hæmorrhage and a rapidly growing tumour rather than by pain which is usually a late symptom dependent on pressure upon other organs

7 *Biliary colic and distended gall bladder* may be mistaken for right renal colic and enlarged kidney, but the colic

is hypochondriac and seldom penetrates much to the back. Examination of the urine and of the excreta will assist much in the diagnosis. The occurrence of jaundice and light-coloured stools and the discovery of gall-stones among the fæces would indicate the cause of the colic.

8. *Caries of the spine*, especially in children, may give rise to one-sided backache and radiating pains in front as a lumbar abscess is gradually forming, very similar to what is met with as the result of renal calculus. The pressure of the abscess on the renal vein may even cause hæmaturia, as I once saw very remarkably demonstrated some years ago. I was asked to go to Thetford to meet Dr. M. Beverley of Norwich in regard to the daughter of a medical man. She had spinal disease in the lower dorsal region and lately had been passing blood with her urine. I found a large lumbar abscess which I opened and drained. The blood entirely disappeared from the urine on the second day after the operation. A few months later I received a letter from the father to say that hæmaturia had again appeared. I wrote back: "Look out for an abscess on the other side of the spine." This was discovered and opened when the hæmaturia again and finally disappeared. I have seen this young lady as a plump well-developed woman showing little or no evidence of the serious illness which she passed through at the age of nine years.

9. *Colic of the appendix cæci* is another condition that I have known on more than one occasion to be confounded with right renal colic. The appendix varies so much in size and position—one was shown at a meeting of the Anatomical Society last year nine inches in length and directed upwards under the liver—that it is not always easy to ascertain whether the colic takes origin in the appendix or pelvis of the kidney and ureter. The ordinary cases of appendicitis are generally sufficiently indicated by the signs of localised peritonitis, tenderness, fulness, and partial obstruction, but it is not these cases that are most liable to be confused with renal colic. The cases to which I refer are those which give rise to little or no signs of inflammation but depend upon irregular spasmodic contractions of the muscular coats of the appendix in their endeavour to expel some fæcal contents, concretion, or foreign body. Only in January last I removed an appendix from a young man who had had constantly recurring attacks of pain every few weeks for a period of four years. On exposing the appendix no adhesions were found but it was noticed to have an enlarged extremity. When removed and split up a small haddock bone was found lodged in the cæcal end which had been the source of all his trouble. Cæcal colic is generally to be distinguished from renal colic by its lower position and by being confined to the front of the abdomen, whilst the tender appendix can usually be felt and rolled under the fingers.

From the criticism of the various symptoms of stone in the kidney and the illustrations which I have given it will be concluded that too much stress must never be given to any one symptom, since no one taken alone is either constant or trustworthy; but the surgeon must weigh in an even balance the various possibilities and gather from such signs and symptoms as may present themselves the probable cause of their origin.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle:* Dr. E. Wieland has been recognised as *privat-docent* of Children's Diseases.—*Bonn:* A very large ophthalmic clinic has just been erected. It will be opened for use at the beginning of the summer session.—*Breslau:* Dr. Karl Ludloff of Königsberg has been recognised as *privat-docent* of Surgery—*Copenhagen:* Dr. E. Faber has been recognised as *privat-docent* of Medicine.—*Greifswald:* Dr. Sophus Ruge has been recognised as *privat-docent* of Ophthalmology.—*Jurieff (Dorpat):* Dr. S. Miknoff of St. Petersburg has been appointed Professor Extraordinary of Midwifery and Gynæcology. Dr. R. Weinburg has been recognised as *privat-docent* of Anatomy, Dr. von Bönninghausen-Budberg as *privat-docent* of Surgery, and Dr. J. Meyer as *privat-docent* of Gynæcology.—*Lausanne:* Dr. G. Rossier, *privat-docent* of Midwifery, and Dr. M. Muret, *privat-docent* of Gynæcology, have been promoted to Extraordinary Professorships.—*Lund:* Dr. G. W. Tornqvist has been appointed *privat-docent* of Surgery.—*Marburg:* The rank of professor has been granted to Dr. W. von Lingelsheim, *privat-docent* of Hygiene.

The Lumleian Lectures

ON

INFECTIVE ENDOCARDITIS MAINLY IN ITS CLINICAL ASPECTS.

Delivered before the Royal College of Physicians of London on March 26th and 31st and April 2nd, 1903,

BY T. R. GLYNN, M.D., F.R.C.P. LOND.,
PROFESSOR OF MEDICINE IN UNIVERSITY COLLEGE, LIVERPOOL; CONSULTING PHYSICIAN TO THE LIVERPOOL ROYAL INFIRMARY.

LECTURE III.[1]

Delivered on April 2nd.

MR. PRESIDENT AND GENTLEMEN,—At the close of my last lecture I was considering the symptoms of infective endocarditis and was directing attention to the anomalous forms of the disease and to the fact that these may run a fatal course with little or no pyrexia.

Excessive perspiration was a marked symptom in many cases. Two men and one woman suffered so much with this symptom that the clothes were changed three or four times in the 24 hours.

Most of my patients were in a very blanched condition on admission, the anæmia being more marked than is usual in advanced disease of the heart with cachexia. In many instances, in patients with cardiac symptoms, the presence of profound anæmia excited a suspicion as to the nature of the disease. The pallor is, I think, usually most marked in the chronic cases and rapidly increases, so that the subjects sink into a state of profound cachexia, resembling that met with in pernicious anæmia, chronic phthisis, and cancerous affections. The examination of the blood carried out in several cases indicated that the anæmia was rapidly progressing. In one case, that of a female, the red blood corpuscles, soon after admission, equalled 3,000,000 per cubic millimetre; in about three weeks they were 2,060,000 and the hæmoglobin fell from 50 to 35 per cent. Her temperature was not excessive. There was an increase in the number of leucocytes in all cases except two. One or more joints became temporarily painful with or without swelling in eight cases.

Epistaxis was an early symptom in six cases and occasionally recurred, once with such severity that it contributed to the fatal termination. Petechiæ were present in ten cases, most commonly distributed on the trunk and legs; in one they were present on the face, in another on the upper extremities and eyelids, and in a third on the mucous membrane of the mouth. In one case only hæmorrhages were found on the retina, but the fundus of the eye was not systematically examined. A papular eruption was observed in one case and an erythematous eruption in another. In two cases there was superficial sloughing of the gums and throat.

Diarrhœa was present in 35 cases. In several it was an early symptom; in two cases it occurred three months before admission into the hospital and was the symptom for which relief was sought. Both these patients were intemperate and, besides the chronic valvular trouble, suffered from kidney disease. One died from uræmic coma preceded by asthma and the other from pneumonia. The intestines were in a catarrhal condition in many instances and hæmorrhagic patches were common. In one case small ulcers were present in the small intestine. In some cases the diarrhœa was severe and the evacuations were dysenteric, but in the majority of cases it was only slight—that is, it was limited to occasional loose discharges once or twice a day.

In about 15 cases there was vomiting, sometimes of an obstinate character. A case referred to by Dr. W. S. Kirkes emphasises the prominence occasionally assumed by the gastro intestinal symptoms. A man was admitted to St. Bartholomew's Hospital with the ordinary symptoms of rheumatism, and developing ulcerative endocarditis, who suffered from diarrhœa and vomiting to such an extent that Dr. G. Burrows, under whose care he was, suspected that he was the victim of an irritant poison administered by his friends. In all cases where vomiting was severe the stomach was found to be injected and occasionally superficial hæmorrhages and erosions were present. In one case a chronic ulcer was found in the lesser curvature. Vomiting and diarrhœa are sometimes present in the final stages of chronic heart disease and cannot, therefore, be regarded as more than suspicious symptoms. In 60 cases of advanced heart disease I found vomiting occur in 16·6 per cent. and diarrhœa in 10 per cent. In the infective form vomiting was noted in 25 per cent. and diarrhœa in 53 per cent.

---

[1] Lectures I. and II. were published in THE LANCET of April 11th (p. 1007) and 18th (p. 1073), respectively.

Albuminuria and hæmaturia are common in infective endocarditis. In my cases the urine was albuminous in 29 instances, and 15 of these contained blood. The frequent occurrence of blood and albumin is sometimes the result of infarctions and sometimes of inflammatory changes. The fact that the average weight of the kidneys in the series of chronic endocarditis was 5·2 ounces and in the infective series 6·9 ounces indicates that parenchymatous changes were commoner in the latter. In my cases the condition of the kidney was frequently described as cyanotic or as large, firm, and congested. In eight there was distinct macroscopic evidence of nephritis.

With regard to the effects of renal infarction, the late Dr. W. M. Ord[2] and Dr. G. Schorstein[3] have each published a case of infective endocarditis with recent infarcts in the kidneys unattended with the presence of blood or albumin in the urine and in one of my patients a similar lesion occurred without any clinical phenomena.

Enlargement of the spleen, a valuable physical sign of the disease, was almost invariably present. In comparing the size of the spleen in 64 cases of simple disease of the valves and in the same number of cases of infective endocarditis, the average weight in the former proved to be 8·9 ounces, the minimum being 2 ounces and the maximum 26 ounces; while in the latter the average weight was 14 9 ounces, the minimum being 7 ounces and the maximum 55 ounces. The spleen in the chronic infective cases was usually larger than in the acute cases and often quite firm. In two of my patients a tumefaction of the spleen was one of the first symptoms to arrest attention. Several instances are recorded where the spleen in infective endocarditis has assumed enormous proportions—one a case under the care of Sir Lauder Brunton and another under the care of Dr. C J. Macalister, whose patient, a boy, aged 11 years, was admitted into the Royal Southern Hospital, Liverpool, suffering from what at the time was thought to be leucocythæmia. His spleen was greatly enlarged, extending to the pubes, and now and again he had febrile paroxysms lasting for a few days. Subsequently he was seized with severe rigors and vomiting, the temperature rose to 107° F., and a loud mitral murmur was noted. He was treated by sulphocarbolate of sodium and gradually recovered, but the mitral murmur remained He was seen four years later by Dr. Macalister and was then suffering from [illegible] red to be [illegible] curs in a [illegible] swelling, and the development of friction sounds over the organ, or when embolism of a kidney takes place and gives rise to pain and the appearance of blood in the urine, valuable indications of the nature of an endocarditis are afforded.

The endocardial murmurs in many of my cases were not due to the recent endocarditis, nor, indeed, were they modified by it, but were the consequence of the chronic lesions. For example, in the instance of the subject of abscess of the myocardium the stethoscopic signs were due to the mitral stenosis and the physical signs in the cases of malformation arose from the congenital defects and were in no way dependent upon the acute endocarditis. The development of excrescences in certain situations, as on the ventricular surface of the anterior mitral cusp and in the cavity of the left auricle, could not be attended with any stethoscopic signs; the murmurs noted in these conditions were due to the aortic and mitral regurgitation which preceded and determined the localisation of the infective process and in the absence of these chronic or congenital lesions the infective endocarditis could hardly have been recognised.

Although physical signs pointing to the development of destructive lesions of the heart are necessarily more commonly met with in ulcerative cases of endocarditis, some variation in the character of murmurs may occasionally be noted in the more chronic forms of the disease. In a lad, aged 17 years, when he was first examined a systolic murmur was limited to the apex. At the end of five weeks his temperature became normal and he went home. As he did not gain strength he returned to the hospital in six weeks when it was found that the heart had become more dilated, the apex beating five inches from the mesial line, instead of four, its former position. Double aortic murmurs were audible and the pulse had become characteristically jerking. After death no ulceration of the aortic cusps was discovered, but a crop of vegetations had developed on the valves which were otherwise healthy. The mycotic disease appeared to have originated on the sclerosed mitral cusps and subsequently to have invaded the aortic segments. Another youth, aged 19 years, when he entered the hospital had a very loud systolic murmur at the apex, audible in the back and all over the præcordium, replacing the first sound and accompanied by a thrill. Ten days afterwards a diastolic aortic murmur developed. At the necropsy the mitral orifice was found to be greatly widened, the left auricle and ventricle being much dilated; the majority of the chordæ tendineæ were ruptured and covered with warty growths and a few recent vegetations were found on the aortic valves. Here, as in the last case, the primary disease was probably seated at the mitral orifice and the aortic cusps became subsequently involved. In another lad a diastolic murmur developed in a similar manner. In a fourth patient a systolic murmur increased in intensity and many of the chordæ tendineæ were found to be destroyed. A female patient had a pre-systolic murmur on admission; in ten days it gave place to a musical systolic bruit. The lower edge of the anterior mitral cusp was found to be detached by ulceration. A sixth patient, admitted with the physical signs of free aortic regurgitation and with double murmurs over all areas, developed a musical systolic murmur. In one or two [illegible] became musical and [illegible] ured and everted. In [illegible] n the sounds occurred and no explanation of the phenomenon could be discovered. At the necropsy the left ventricle was enormously dilated. The most [illegible] modification of the heart sounds wa[illegible] murmur. In a case of acute [illegible] ch I attended with Dr. R. R. [illegible] f an affection of the heart was the development of an aortic systolic murmur; a[illegible] afterwards a diastolic murmur occurred and th[illegible] ith the ordinary chronic le[illegible] may, as the structures [illegible] suddenly undergo great alteration [illegible] is description are not in[illegible] of the aortic cusps. A [illegible] ed 30 years, who as the [illegible], before had suffered from [illegible] endocarditis and developed double aortic murmurs. Two months after his first visit the diastolic murmur had become so loud and musical that it annoyed him when he lay down at night. He was otherwise well. An old man was once brought to consult me by his wife who complained that there was something twanging in her husband's chest which kept her awake. Here, too, a simple diastolic murmur which I had heard on a previous occasion had become [illegible] of the heart sounds are so [illegible] that the temperature of [illegible] ould be taken for several days to exclude the possibility of the disease being present.

An alteration in the character of the pulse tracings was noted in several cases. In two cases the pulse wave assumed the characteristics of aortic obstruction and the aortic valves were found to be covered with fungating growths. Another showed a similar tracing when admitted and a like lesion was discovered at the necropsy.

In several of my patients there was evidence of rapid dilatation of the heart, but as this symptom is to be noted in progressive cardiac cachexia it is not, taken alone, of much value as a diagnostic sign in infective cases.

The great majority of my cases were of chronic type, the symptoms of the infective disorder persisting for several months. One case extended over eight months; the patient was in the hospital for seven months and his illness commenced some weeks before he entered. Four cases were under treatment for six months and these had been suffering from one week to two months before entering the hospital from diarrhœa, sweating, pain in the joints, or epistaxis, so that the disease was also in these cases of long duration. Five cases were under my care between four and five months, eight between two and three months, and the remainder were in the hospital under one month. In the majority of these cases there was a history of illness of some weeks' duration before admission.

[2] THE LANCET, April 14th, 1833, p. 724.
[3] THE LANCET, March 20th, 1597, p. 811.

When the affection commences insidiously without initiatory rigors, as is frequently the case in the chronic forms, it is difficult to ascertain the date of the period of invasion and therefore to estimate the duration of the disease. In many cases, however, some idea of the duration of the disorder before coming under observation was acquired from the history of night sweats and diarrhœa. Rigors were an early symptom of infection in a few cases only. In two cases—the patient in one case being a plumber and in the other an intemperate man—the symptoms of invasion pointed to acute renal trouble, there being pain in the back and scanty dark-coloured urine which on examination was found to contain blood. In two other cases the first serious manifestation was an attack of syncope, in one five and in the other six weeks before admission. The earliest symptoms in 12 cases were diarrhœa and night sweats commencing from three weeks to four months before admission; all these patients were very pale, weak, and emaciated on entering the hospital. In 15 instances relief was sought for an aggravation of some previous manifestation of chronic disease of the heart or for the sudden development of such indications—namely, œdema of the lower extremities, palpitation, cough, and dyspnœa. Sometimes these symptoms were associated with night sweats or gastro-intestinal disturbance and renal trouble.

Cerebral embolism proved fatal in six cases and cerebral hæmorrhage in five. One patient died suddenly in convulsions and after death a large hæmorrhage was found in the head of the pancreas between it and the duodenum. Death was due to pneumonia in 18 instances and to acute pleurisy in two cases. In many of the cases of pneumonia the affected lung was in a state of grey hepatisation. Two patients died suddenly with symptoms resembling angina; in one the coronary arteries were blocked by calcareous deposit, while in the other, who screamed with pain in his chest just before death, the coronary arteries were closed by recent vegetations. Five patients died suddenly; in these the aortic valves were seriously involved. Death in 14 of my cases appeared to be due to the cachectic condition to which the patients were reduced, brought about not only by the septicæmia but also by the physical trouble and degeneration of organs associated with advanced heart disease. Five died with uræmic symptoms. Dr. W. Hale White has referred to uræmia as a frequent cause of death in infective endocarditis and has described a case of this disease associated with kidney trouble where the temperature was normal for three or four weeks, the renal disease, as in several patients under my care, masking the heart affection.

The difficulties attending the diagnosis of endocarditis are sometimes insuperable, for trustworthy clinical indications may be wanting I have already referred to the anomalous character of the temperature in certain cases, more particularly in those of the chronic class, and to the occasional absence of fever even in subjects of the acute type of the disease M. Claude[4] published two cases of malignant endocarditis without pyrexia. The patient in one of these cases entered the hospital with dyspnœa, albuminuria, and hypothermia The râles from bronchitis prevented satisfactory auscultation of the heart sounds. Death occurred from coma. The necropsy revealed ulcerative and vegetative lesions of the aortic valves. In this case and in the other presenting the same peculiarity streptococci were found in the vegetations and at the base of the ulcerations. In a patient under the care of M. Petit[5] suffering from ulcerative endocarditis there was also an absence of pyrexia and of stethoscopic signs. Dr. Hale White refers to the influence which disease of the kidneys exerts on the symptoms of infective endocarditis, the kidney trouble overshadowing the heart trouble, and he gives the history of a case of infective heart disease with slight pyrexia on admission and the absence of fever for three or four weeks subsequently, the urine all the while being albuminous, sanguineous, and of low specific gravity. In M. Petit's case just referred to it is stated that the kidneys were affected and that the patient died from dropsy and exhaustion. Dr. Leslie Phillips[6] has published two cases of infective endocarditis with Bright's disease where the temperature did not rise above normal during the last days of life. Dr. A. E. Sansom[7] notices the absence of pyrexia in an otherwise typical example of infective endocarditis. Kirchensteiner[8] relates a case of pneumococcic endocarditis where pyrexia was absent until a few days before death. Sometimes, and especially in acute cases, the recognition of the disease is rendered impracticable by the non-existence of the physical signs of endocarditis. The late Dr. J. Curnow[9] published the case of a patient in whom the physical signs of heart disease were absent and who appeared to be suffering from pyæmia or severe typhoid fever. The late Dr. Julius Pollock[10] described a case of ulcerative endocarditis where there was neither enlargement of the heart nor murmurs. Mr. Laurence Humphry[11] gives particulars of a similar case. Examples of infective endocarditis with an absence of evidences of heart trouble have also been met with by Lancereaux, Harlitz, Sanguine, Purser, and others. The occasional absence of endocardial murmurs in infective endocarditis is to a large extent due to the fact that the edges of the curtains of the valves are not invariably involved.

When the valves of the heart are involved in a primary or secondary affection, originating in pneumonia, typhoid fever, or urethritis, or in some local or general condition capable of causing infection, the development of a murmur or other sign of endocardial trouble is of great diagnostic value, and the significance of the physical sign is increased if it is attended by a renewal, or alteration in the type, of the pyrexia. At the same time it must be borne in mind that disorders capable of exciting malignant endocarditis may also give rise to the affection in its simple form and further that functional murmurs often occur during the course of an exhausting febrile malady. I have notes of a case of pneumonia in a woman where the resolution was unusually delayed and where a murmur declared itself over the mitral area during the third week, when the temperature was hectic. For a short time there was little improvement in the local or general conditions, but convalescence was slowly established and when she left the hospital the heart sounds were almost normal.

In the complex conditions due to acute general infection with secondary manifestations in several organs, endocarditis, if present, may fail to develop to an extent capable of recognition. The following case of acute pneumococcic infection with endocarditis and other lesions, kindly reported to me by Dr. W. Carter, illustrates the conditions referred to. A man, aged 40 years, entered the Royal Southern Hospital, Liverpool, on Dec. 1st, 1902. His illness had commenced three days before with shivering, frequent cough, and high fever, and he presented the ordinary features of pneumonia. A few days after admission he became hemiplegic, then unconscious, and finally died. No endocardial murmurs were present at any time. At the necropsy there was evidence of acute meningitis. The left lower lobe of the lung was in a state of red hepatisation. On the left posterior aortic cusp was a tuft of vegetations of about the size of a pea, soft, friable, and easily detached. The spleen was enlarged and the kidneys were congested. Pneumococci were found in the pus from the meninges, in the consolidated lung, and in the vegetations.

In less acute cases of septicæmia associated with pneumonia the type of the pyrexia may change on the advent of the endocarditis or a murmur may be noted. A man about 30 years of age, the victim of chronic bronchitis and emphysema, a patient of Mr. A. E. Davis of Liverpool, was attacked with pneumonia. On the tenth day there was some indication of a crisis, but the temperature soon became high again and the pulse more rapid. A soft systolic murmur developed at the apex and a day or two afterwards he became hemiplegic and aphasic, gradually sank into a comatose state, and died.

In the absence of positive symptoms the diagnosis depends on the ability to exclude all affections other than acute endocarditis likely to cause pyrexia, a method of investigation calculated at times to be attended with failure, as the following cases demonstrate A man, aged 51 years, of intemperate habits, was admitted into the hospital under my care in 1901 with albuminuria, irregular pyrexia, and evidence of aortic and mitral disease The spleen was felt below the costal arch There were emphysema and expectoration of mucus, he died in ten days At the necropsy the aorta was atheromatous and its valves were incompetent, but there was no recent endocarditis The pyrexia was due to the presence of miliary tubercles in the lungs Another patient, a woman, aged 28 years, was admitted in 1898 She was intemperate and had suffered from rheumatism three years before, she had lately complained of weakness, shortness of breath, and palpitation. On admission her temperature was 104° F, she was very anæmic, cyanosed, slightly jaundiced, and prostrate, there was evidence of slight alcoholic neuritis, the heart was dilated and hypertrophied, with a systolic murmur at the apex the spleen was enlarged, and the urine was albuminous The temperature remained high, between 105° and 106°, till the day before her death, and a petechial eruption appeared on the legs At the necropsy the pericardium was found to be adherent, the heart enlarged, and its muscle pale and soft, the mitral orifice was dilated but the cusps were normal The spleen weighed 20 ounces and was very friable, the kidneys were enlarged and mottled, the lungs intestines, and other organs were in a normal condition Streptococci were found in the spleen by cultivation The case was one of septicæmia developed in an intemperate, unhealthy woman, but no primary focus of infection was discovered, and the heart, though unsound, was in no way involved in the septic process A man, aged 39 years, entered the hospital with pains in the joints, evidence of heart disease, slight irregular pyrexia diarrhœa, and sanguineous urine Streptococci were found in the blood, death occurred in three weeks At the necropsy there was simple thickening of the mitral cusps but no recent endocarditis He also died from septicæmia but the heart was not involved

When infective endocarditis develops in apparently healthy individuals the manifestations of general infection dominate over the symptoms of endocarditis, indeed the physical signs of disease of the valves may be absent for a few days and the difficulties attending diagnosis commensurately increased This was the course of events in a case I attended with the late Dr R Pugh in Liverpool some years ago A girl was suddenly attacked with high fever and delirium, nothing was found pointing to disease of the heart or lungs, and it was not until a week after the illness commenced that evidence of endocardial mischief appeared in a mitral systolic murmur and was followed by other symptoi

Wher a complication of as in many of my cases, the symptoms of septicæmia are often ill pronounced and masked by the troubles originating in the embarrassed circulation Occasionally the affection even in apparently healthy persons, commences in an insidious manner The following is a good example of this mode of invasion Many years ago a young surgeon and valued friend presented himself to me for examination in connexion with a proposal for life insurance A mitral systolic murmur was present with slight displacement of the heart's apex There was no history of rheumatism For about six years subsequently he was actively engaged in private and hospital practice and at the end of that time he called to consult me about his health He had he said been feeling out of sorts for about two months, had lost his energy and appetite and had suffered from sleeplessness and occasional night sweats His idea was that he was a victim of neurasthenia and with the view of trying what exercise would do for him he had been away for a fortnight on his bicycle He was anæmic his pulse was rapid and his temperature was 100° F, the apex beat of the heart was more displaced than on my former examination and the mitral murmur was more marked With considerable difficulty he was persuaded to stay at home and to give up work. Our impression as to the nature of his case became gradually confirmed as the pyrexia continued and the exhaustion increased For two or three weeks he struggled against his weakness spending his days on the sofa and sitting up to his meals The fever pursued an irregular and intermittent course, usually falling to 99° in the morning but rising to 102° later in the day In about six weeks absolute rest in bed became imperative Aortic murmurs developed, the spleen became enlarged, vomiting occurred occasionally, albumin appeared in the urine, certain joints became painful, petechiæ showed themselves, and an acute pleurisy developed Asthmatic attacks accompanied by palpitation and pain over the heart, disturbed his nights, his appetite failed entirely, and he sank into a comatose state and died after an illness of three or four months' duration

In my first lecture I referred to a case of infective endocarditis following chlorosis where also the infection developed in an insidious manner and I believe that the disease not infrequently commences in this obscure way, its mode of invasion being in these instances utterly unlike that described in text books as characterised by rigors, high fever, and delirium

I have referred to a case of infective endocarditis which was mistaken for typhoid fever In another patient who was sent to the hospital as suffering from enteric fever, the fever was of continued type, so that the resemblance to typhoid fever was greater than in the former patient where the pyrexia followed an intermittent course The state of the heart the great enlargement of the spleen, the hæmaturia the presence of staphylococci in the blood, and the negative result of the serum reaction, all served to indicate the nature of the disease

Though the serum reaction is calculated to be of great assistance in cases of this description it may sometimes be misleading A case of great interest is related by Dr W R. Matthews [12] of infective endocarditis with ulceration of the mitral valve where the serum reaction gave a positive result and where the appearance of the intestines did not point to a previous attack of typhoid fever Dr Hale White and Mr W O O Pakes have also met with a case of malignant endocarditis giving the serum reaction and cases are recorded where this reaction has been positive in septicæmia and acute tuberculosis [13]

I am indebted to Dr Peter Davidson for the history of a patient of his where the clinical evidence was unusually conflicting A man had rheumatism at the age of 21 years, in 1900 12 years afterwards, his heart was dilated and a slight systolic murmur was noted over the aortic area Two years subsequently he was attacked with chills and fever, staphylococci were found in the blood, and the serum reaction was negative In four days the temperature became normal and remained so for three days, the pyrexia then returned, and on the fourteenth day he developed typhoid spots The serum reaction was now positive, the spleen became enlarged, pericarditis and pneumonia set in and the patient did

I have already referred to a case of acute tuberculosis associated with disease of the heart where an error of diagnosis occurred There is a close resemblance between chronic tuberculous disease of the lungs and chronic forms of infective endocarditis In both the onset may be insidious and the symptoms similar—namely, anæmia, wasting debility, slight pyrexia, and pulmonary troubles Careful phys blood and sp be formed of the valves accompanies resultant symptoms necessarily conform to the chronic type of infective endocarditis Fortunately, in such complicated cases examinations of the apices of the lungs and sputum usually furnish reliable indications of the nature of the disease and disclose the origin of the pyrexia. In one of my cases chronic tuberculous disease of the lungs was associated with infective endocarditis The disease of the valves of the heart was due to streptococcic infection and not to infection by the tubercle bacillus. I say nothing of tuberculous endocarditis an affection that has excited much attention during the last few years on the Continent for I have met with no examples of the disorder and have searched the records of the post mortem examinations held at the Liverpool Royal Infirmary without finding a single instance of it.

The protracted forms of infective endocarditis present a close resemblance to pernicious anæmia and the likeness is the closer since streptococci may be found in the blood of the subject of either disease In 1887 a man aged 50 years was under my care suffering from pernicious anæmia. His temperature was hectic in character, the heart was greatly dilated, with loud systolic murmurs at all areas, and there were marked gastro-intestinal troubles and great enlargement of the spleen, the case perhaps being one of splenic rather than of pernicious anæmia. A correct diagnosis was arrived at chiefly on the evidence furnished by the history of this illness, the gradual development of the symptoms of heart trouble, and of pyrexia.

[12] Brit Med Jour Jan 21th, 1899

[13] Ibid 1902 p 715.

Cardiac thrombosis and embolism associated with chronic disease of the heart are not usually attended with pyrexia. I have, however, met with two instances where these conditions were associated with fever—in one a softening thrombus was situated over a suppurative focus in the myocardium. The symptoms presented by the patient resembled those of infective endocarditis. In the other case a softening thrombus was found on a sclerosed mitral cusp and here again the symptoms were almost identical with those of malignant endocarditis.

With regard to the cultivation of bacteria from the blood during life my own experience coincides with that of others who have occasionally obtained a negative result even when several cubic centimetres of blood have been removed from a vein, especially in cases of a chronic character. The occurrence of leucocytosis may help to distinguish infective endocarditis from typhoid fever. I have, however, as I have before stated, met with two cases of infective heart disease without leucocytosis.

Recovery in infective endocarditis is a rare event and the more acute the disease the less is the probability of a favourable termination. Moritz considers that the disease proves fatal in 80 per cent. of the cases and these figures appear to me rather to underrate the mortality. The evidence that the affection may occasionally end favourably is of two kinds, pathological and clinical. I have already referred to the former and have described anatomical conditions indicative of a healing process, usually partial, but occasionally complete. The clinical evidence alone remains to be considered. I have alluded to the case of a boy who entered the hospital with a diffuse aneurysm of the forearm and symptoms of infective endocarditis and who recovered and died 19 years afterwards from chronic disease of the heart. I will now refer very briefly to one or two other cases where recovery has taken place. In one, a man, aged 20 years, was admitted into the hospital under my care on Jan. 1st, 1900, with aortic and mitral regurgitation. He had suffered from rheumatism at the age of 19 years and had been in the hospital on a former occasion with symptoms of rheumatism and heart disease. Three weeks before entering the hospital he commenced to suffer from breathlessness, palpitation, weakness, night sweats, and œdema of the feet and ankles. He was very anæmic; his temperature for 18 days was 101° or 100° F. at night and about 99° in the morning. There was no evidence of rheumatism or of any lung trouble to account for the pyrexia. The area of splenic dulness measured four inches; the urine was free from albumin but there was a tendency to diarrhœa. Cultures of blood taken from a vein showed staphylococcus albus and staphylococcus aureus. Three weeks after admission his temperature became normal and he left the hospital early in March—that is, two months from the time of his admission. The following case appeared to be an infective endocarditis following parturition and ending favourably. A woman, aged 28 years, was confined of her first child two months before admission to the hospital. Eight days after confinement she had a rigor and rigors were frequently repeated during the following weeks. On admission she was thin and blanched and wet with perspiration; her expression was dull and heavy, her mouth was open, and her tongue was dry; the left ankle was swollen and the skin in its neighbourhood was œdematous; the pulse was small (116) and the area of cardiac dulness was increased. The apex beat was four and three-quarter inches from the mesial line, with faint systolic murmur in the mitral area. The splenic dulness was increased; the urine was free from albumin. Dr. Grimsdale, obstetric surgeon to the hospital, found nothing abnormal in the pelvic organs. The rigors were frequently repeated during the first five days of her sojourn in the hospital. The sweats were most profuse, so that her clothes were changed half a dozen times during the 24 hours. Her temperature was of a very irregular type, for the first week being hectic in character, touching 101° F. with a rigor, and then falling to normal. During the second week the pyrexia followed a more continued type, seldom falling to 99°, and with a rigor reaching 104°. During the second week there was increase in the size of the heart and the mitral murmur became more marked. Staphylococci were found in the blood taken from a vein. There was much nausea, the appetite failed completely, and there was much pain of a wandering character in the joints. At the end of six weeks she commenced to improve. The inflammatory trouble in the left ankle-joint, which at one time appeared likely to end in suppuration, receded, and the temperature became normal two months after admission. She left the hospital three weeks later, and at that time the apex beat of the heart was three and a quarter inches from the mesial line, and the first sound was clear everywhere. A man, aged 51 years, was admitted under my care in 1876 with symptoms of aortic regurgitation. He had suffered from rheumatism at the age of 30 years. He complained of breathlessness, palpitation, and weakness. There was no œdema of the extremities. The pyrexia was of an irregular type, sometimes highest in the evening and at other times in the morning, ranging between 99° and 102° F.; the urine was albuminous. On one occasion he had a sudden sharp pain over the spleen which became enlarged. There was diarrhœa, the bowels acting five or six times in the 24 hours. In about three weeks his temperature became normal, the diarrhœa ceased, and the albumin disappeared from the urine. He soon afterwards left the hospital, the symptoms of chronic heart trouble still persisting. A young woman, aged 22 years, was admitted on Sept. 5th, 1887; she was under-sized and anæmic, with emphysematous chest and varicose veins on the legs. The red corpuscles were 2,000,000 per cubic millimetre and the hæmoglobin was 50 per cent. She had suffered from three attacks of rheumatism and lately had menorrhagia. The present illness commenced with epistaxis four days before admission. The heart was enlarged and there were mitral and aortic murmurs. The spleen was also much enlarged, its area of dulness measuring six inches. She suffered from diarrhœa with sanguineous dysenteric motions, epistaxis, petechial hæmorrhages on the skin, and albuminuria. Her temperature was of a hectic type, generally being 103° F. in the evening. She gradually improved under treatment and was convalescent in six weeks. A man, aged 28 years, entered the hospital with pain and swelling of the ankles, chronic bronchitis, and emphysema. He had had one or two rigors a month before admission. For about a fortnight his temperature was very high and of a hectic type, usually reaching 104°, even 105°, and once 107° F. in the evening and falling to normal or subnormal in the morning. Staphylococcus albus was found in the blood on two occasions. The heart was enlarged and had a mitral systolic murmur at the apex. The splenic dulness was increased. There was no diarrhœa or albuminuria. At the end of three weeks the pyrexia began to diminish. He gradually improved and left the hospital convalescent at the end of two months. I am indebted to Mr. A. M. Watkins of Whitchurch, Salop, for notes of a case apparently of infective endocarditis terminating favourably. A girl while suffering from broncho-pneumonia exhibited signs of mitral regurgitation. At the same period there were high fever, rigors, and sweating accompanied with incessant vomiting. These symptoms continued for many weeks; dropsy developed and two months after the onset of the illness several severe attacks of angina occurred. It was many weeks before the temperature became normal and six months before convalescence was established. She was treated by large doses of quinine, from 20 to 40 grains per day, the drug for many days being administered by the rectum owing to the incessant vomiting. Dr. Nathan Raw also has obliged me with particulars of a case of recovery in which the patient was a girl, aged 10 years, who had suffered from rheumatism three years before and had never felt well since. She entered the Mill-road Hospital at Liverpool on Feb. 3rd, 1902, complaining of severe pain under the left breast. The heart was dilated and there were double mitral murmurs; the pulse was 120; the trunk and limbs were covered with petechiæ and the respirations were 24. There were cough and expectoration. The urine was free from albumin. The temperature oscillated between 101° and 104° or 103° F. and remained high for 11 days; at the end of a fortnight it became normal and the patient rapidly recovered. Streptococci were found in the blood in great numbers. She was treated by digitalis and strychnine.

I will not refer to the cases of recovery recorded in the journals; they are comparatively few in number and the treatment adopted has been very various. Occasionally the subjects of the disease recover to a certain extent and subsequently relapse. Three of my patients improved for a time and left the hospital, only to return in a worse condition. This was the case with one patient who suffered from congenital disease of the heart. He was first admitted with irregular pyrexia and diarrhœa and loud systolic murmurs across the sternum—double murmurs, loudest over the pulmonary area. After a month his temperature became normal and his general condition improved, so that he was able to go home. He returned in two months, the former symptoms having become aggravated. He lingered for seven months. Another patient entered the hospital for pains in the joints which started, he said, after a rigor seven weeks before. He was very anæmic and he suffered from sweats, vomiting, and slight irregular pyrexia. In about a month his temperature became normal, not rising above 99° F., his general condition had improved, and he left the hospital. He remained fairly well for a time, only suffering from symptoms due to the chronic affection of the valves, but in about seven weeks he returned. His temperature was now distinctly hectic, a diastolic murmur had developed, the pulse tracings had altered in character, and all the former symptoms had become accentuated. I am indebted to Dr. T. Bushby for what appears to be a relapsing case of infective endocarditis. The patient, a youth, aged 19 years, entered the David Lewis Northern Hospital in 1898 with evidence of aortic and mitral regurgitation after rheumatism eight years previously. The temperature was high for several days, fell to normal at the end of a week, then speedily rose again to 103° F., and a day or two later to 105°. It remained high for another week and fell again, only to rise at a subsequent period. There were several exacerbations of this description. In three months he was able to leave the hospital. During his illness the spleen became enlarged, its area of dulness measuring four and a half inches. On one occasion it increased in size and became the seat of pain. No organisms were found in the blood. The urine was for a time albuminous. He remained out of the hospital a month and then returned with pyrexia of a more regular type. On this occasion he suffered from vomiting and the spleen remained enlarged. The temperature gradually fell, but it was ten weeks before it became normal and 17 weeks before he was able to leave the hospital. He remained well for two years, when he again broke down, attributing his illness to losing a situation and want of food. At the end of this period he again came under Dr. Bushby's care with symptoms similar to those presented on former occasions. The pyrexia this time continued for four months and again yielded to treatment.

Sir Douglas Powell in the Lumleian Lectures of 1898 carefully considered the circumstances that govern the treatment of infective endocarditis, directing attention to the necessity of observing certain prophylactic precautions during convalescence in rheumatic endocarditis and reviewing the therapeutic measures likely to be of some use in the disease With regard to prophylaxis he points out that while infective endocarditis "is frequently started from infection through septic surfaces or centres, in other and a numerous class of cases the disease arises without any intermediate illness from sewer gas emanations, but in the latter cases in my experience it has almost always happened that previous valve lesions from former endocarditis have existed." It is evident, therefore, as Sir Douglas Powell points out, that patients convalescent from rheumatic fever or with simple valvular affections should be protected from possible exposure to sewer gas emanations. Dr. Peter Davidson supplies me with a case in point. He had for some years under his care a man with congenital heart disease. With care and appropriate treatment he was able to lead an active life. In the discharge of his duties, however, he was on one occasion compelled to spend some days in the examination of house property; he was fatigued and possibly, Dr. Davidson thinks, exposed to deleterious influences in insanitary dwellings. While occupied in this way he became ill; febrile symptoms developed, streptococci were found in the blood, and he died from infective endocarditis. The same conditions probably occasioned the genesis of the disease in a patient whom I saw with Dr. J. O'Hagan of Liverpool in 1901. The patient, a young man, just convalescent from an attack of rheumatism, went on a business journey to America and there spent much time in travelling. During his expedition he became very ill and developed right hemiplegia and aphasia; on his arrival home he presented the symptoms of infective endocarditis and died from pneumonia.

No specific remedy has yet been found for infective endocarditis. At one time there was reason to expect that such an agent had been discovered in anti-streptococcic serum, but the success attending its use has not been as great as was anticipated. Only a few days ago Dr. Cyril Ogle,[14] gave a comprehensive review of the therapeutic value of this serum, together with statistical information of the successes and failures experienced in its use, from 1896 to 1901 inclusive. Sir Douglas Powell in his Lumleian Lectures of 1898, to which I have already referred, also gave a tabulated statement of the results of treatment by anti-streptococcic serum up to the date of his lecture. In Sir Douglas Powell's table the successes amount to 25 per cent. and in Dr. Ogle's table to 31·5 per cent. It is evident that the anti-streptococcic serum is only likely to be useful in cases of infective endocarditis from streptococcic infection, and that as the serum prepared from one variety of streptococci is destructive of that particular variety only it is desirable to use a polyvalent serum. Even when the serum has been used in appropriate cases the results obtained are not very encouraging. I find in Dr. Ogle's tables that streptococci only were found in the blood in seven cases and that in but two of these was the serum treatment successful. It may be, as Dr. Ogle is inclined to believe, that the injections were not commenced soon enough or that the dose of serum was too small. I am indebted to Dr. Nathan Raw for particulars of his experience in the use of anti-streptococcic serum in the Mill-road Hospital, Liverpool. He used it in five cases of what he considered to be streptococcic infection where the heart was implicated; from 50 to 200 cubic centimetres of the serum were injected in each of these patients without any beneficial results. In one the infective disease followed many attacks of rheumatism; in another erysipelas; in two it succeeded parturition and in the fifth was associated with phthisis. I have obtained no information of an encouraging nature from any other of the large hospitals in Liverpool. I have used the serum without success three times—once in hospital practice, where streptococci were found in the blood, and twice in private practice, where no micro-organisms were discovered on examination. In the case of the patient under the care of Dr J. Hill Abram in my absence the use of the anti-streptococcic serum was attended with the disappearance of the streptococci from the blood. 100 cubic centimetres were injected in ten days, streptococci and staphylococci being present in the blood. After death staphylococci alone were found in the vegetations and spleen.

The most recent remedies, Creda's collodial silver salts and nuclein, do not appear so far to have given very satisfactory results, though recovery in malignant endocarditis is reported to have followed the use of the silver salt on the continent. Nuclein was used together with anti-streptococcic serum by Dr. Hill Abram in his case of infective endocarditis following pneumonia without any benefit.

It is possible that the future may bring improved methods of serum treatment; meanwhile the physician must not adopt [illegible] strength of the patient by the aid of tonics and stimulants, diminish as far as is possible the multiplication of bacteria in the organism by the administration of antiseptics, and strengthen and regulate the action of the heart by cardiac tonics.

In conclusion, I thank you for your kind attention and beg to assure the President and Censors of this College that I am deeply sensible of the honour they conferred upon me in inviting me to give the Lumleian Lectures. I must also thank many friends who have lent me much valuable material.

---

[14] THE LANCET, March 14th, 1903, p. 720

THE DATE OF THE EXAMINATIONS FOR THE ENTRANCE SCHOLARSHIPS AT THE LONDON HOSPITALS.—The Jewish New Year will fall on Tuesday and Wednesday, Sept. 22nd and 23rd next. Judging from past years these days may be chosen for the examination for entrance scholarships at the various London medical schools. It has been suggested to us by a correspondent that the deans of the various schools might well avoid these days as well as all Saturdays in making the arrangements for the examinations, otherwise Jewish candidates are disqualified.

An Address

ON

DIETETICS.

Delivered at the Opening of a Discussion at the West Kent Medico-Chirurgical Society on April 3rd, 1903,

BY ROBERT HUTCHISON, M.D., M.R.C.P. EDIN., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, W.C.

MR. PRESIDENT AND GENTLEMEN,—I wish in the first place to thank you for your kindness in inviting me to open this discussion. At the same time I feel that you have laid upon me a considerable responsibility, for the subject of dietetics is a wide one and to deal with it adequately in the time at my disposal is no easy matter. My task, however, is lightened by your foresight in limiting the scope of the discussion to the *principles* of dietetics, which, I take it, sets me free from the necessity of entering into details and permits a more general view of the subject as a whole. I think, if I may say so, that the society is to be congratulated upon the selection of this theme for debate. Nothing is more striking at the present day than the interest shown by patients and the public in everything that relates to food and diet, whilst the comparative apathy displayed by our profession in such matters is equally noteworthy. Nor has this escaped the notice of the more intelligent of our lay critics. This, for instance, is what a shrewd old lady[1] whose opinions command a large measure of public attention has to say of us in a recent book: "The study of food in relation to health is a branch of medical science as yet in its infancy. ...... Has not the doctor been taught to study drugs for the cure of disease rather than food as the basis of health? He never gives diet much consideration except in the case of over-eating in severe illness. ...... I wish to warn people that if they consult their doctor no diet will be tried. The doctors must be educated by the public." If we are honest with ourselves I think we must admit that those strictures contain a certain amount of truth. In our defence, however, let me hasten to say this, that one main reason why we medical men are often less dogmatic than lay people in matters of diet is that we know better than anyone the truth of the old adage that "one man's meat is another man's poison." It is the foolish layman who is apt to rush in where the angels of healing fear to tread. This factor of personal idiosyncrasy, indeed, is the great stumbling-block in the way of dietetic progress. We can never be quite certain how any given individual will react to a particular kind of food. I have a medical friend, for instance, who is always made violently ill if he eats the smallest particle of plaice, though all other sorts of fish are innocuous to him, and I know another distinguished physician who can eat beef but dare not touch mutton, and everyone here must have met with similar instances. The first point, then, which I wish to make is that the personal factor dominates all dietetic questions and that every change of food must always be more or less of an experiment. Physiologists have not yet arrived at an explanation of these personal peculiarities, but I think that their true interpretation will ultimately be found to lie in individual variations in metabolism. It is extremely likely, in other words, that a man's metabolism varies as much as the colour of his hair or the shape of his nose and that although the end results of metabolism are very much the same in all individuals, yet the steps by which those results are arrived at are capable of infinite variation. My friend Dr. A. E. Garrod[2] has recently brought forward this suggestive view as an explanation of the phenomenon known as alkaptonuria, and no doubt many metabolic diseases can be explained in the same way. Notwithstanding this, I do not think we need give up the attempt to formulate any rules of diet in health and disease in despair. As regards the general principles to be observed science can afford us clear guidance, although in matters of detail there will always be room for differences of opinion and of practice.

Before proceeding to consider the dietetics of disease it will be well for us to have some clear ideas as to the physiology of diet in health. Now, I think that the fussiness—to use what seems the most appropriate word—displayed by many people nowadays about food is not to be commended. As far as possible to take no thought what we shall eat seems the wiser and more excellent way. In particular, I think that arguments based on the character of the human teeth or shape of the alimentary canal as to the food supposed to be "natural" to man are beside the mark. We are no longer savages and it is as "natural" to man in the present stage of his evolution to live under the conditions of civilisation as it was for him at one time to live half naked in a cave. And if our environment evolves, so also must our diet. The fact seems to be that man is pre-eminently an adaptable animal and the healthy man can live upon any sort of diet provided it is capable of digestion and absorption and fulfils two well-defined conditions. These are: (1) that the food yields enough potential energy to supply the daily outgoings from the body in the form of heat and work and (2) that it contains enough proteid to replace the daily and inevitable destruction of tissue. Let us look at these two requirements for a moment.

As regards the amount of potential energy which the food must contain physiologists are quite in accord. Something between 2500 and 3500 calories will be required, depending chiefly upon the nature of the work which the individual has to perform. About 3000 calories would probably represent the requirements of the ordinary town dweller living a moderately sedentary life. Part of this total of energy must be supplied, as we have just seen, in the form of proteid. Whether the rest is to be obtained mainly from carbohydrates or from fats depends largely upon the digestive capacity of the individual and to some extent also upon his purse. Fats are, as a rule, expensive; carbohydrates are cheap and hence the poor man will tend to take a large proportion of his energy from the latter. Amongst the poorer classes, indeed, this tendency is responsible for a certain amount of disease, particularly in children, and by throwing a strain on the carbohydrate-assimilating functions it tends to bring out any inherited tendency to diabetes. Physiologically, as far as the cells are concerned, it seems to be a matter of indifference whether fats or carbohydrates predominate, but ease of digestion seems best promoted by avoiding a preponderance of either. This, too, one can say from the physiological side that the less proteid a diet contains the more should the carbohydrates be increased, for they are more efficient "proteid-sparers"—i.e., they make a little proteid go a longer way in repairing tissue—than are fats.

As regards the second requirement of a healthy diet, that it should contain enough proteid to replace the daily waste of tissue, all physiologists are agreed. Unfortunately, however, there is less accord as to the quantity of proteid necessary for this purpose. Few authorities would now maintain that the amount recommended by Voit—namely, 120 grammes—is absolutely essential, and, indeed, a careful examination of the diet of many apparently healthy persons has shown much lower figures than this. The exact quantity of proteid required seems to vary greatly in different individuals, probably with the bulk of their muscular tissue, and to some extent, also, it depends upon the amount of "proteid-sparers"—particularly carbohydrates—in the diet. What the irreducible minimum, however, below which one cannot go with safety may be we do not know. This is the more to be regretted as the scientific attitude to some systems of diet, such as vegetarianism, must depend to a large extent on the reply to this question.

Habitual use of a diet which fails to conform to the above requirements must inevitably end in disease. The error may be in the direction of excess or deficiency. Amongst the better-to-do of our patients the tendency is to take in too much total energy—i.e., to over-eat. I do not wish to go so far as the Chinese proverb which says that "most men dig their graves with their teeth," but it cannot be denied that many make themselves ill by habitually "doing themselves well." Hence result such diseases as obesity, some forms of glycosuria and dyspepsia, and in many cases also gout and the uric acid group of diseases generally, possibly also arterial and renal degeneration. The popular cry at present is for concentrated foods—the maximum of nourishment in a minimum of bulk—and the makers of patent articles of diet are not slow to respond to the demand. I believe that this is an error. What we want at present is a food which will present a maximum of bulk with a minimum of nourishment—that is to say, one which will fill the stomach whilst starving the tissues. To many overfed persons such a food would be a godsend. At the other end of

---

[2] THE LANCET, Dec. 13th, 1902, p. 1616.

the nervous system, and tuberculosis in all its manifestations.

The results which follow upon an improper proportion of proteid in the diet are less easy to recognise. There is reason to believe, however, that the habitual consumption of quantities of proteid much in excess of what is required to keep the tissues in repair results in some persons in the production of gout and the uric acid group of diseases generally. Probably, also, some cases of chronic renal disease and arterial degeneration may have a similar origin. On the other hand, a diet too poor in proteid seems to bring about a general feebleness of body, for proteid is a great stimulant to the vital activity of the cells, the consequence of which is a lowering of the power of resistance to disease. This may explain the great liability of the native population in India to suffer from the ravages of plague and the comparative immunity of the Europeans whose diet is richer in proteid. I am told, also, by those who have good opportunity of judging that the lower classes in Italy, whose diet is very poor in nitrogenous matter, are very apt to go down before the assaults of acute infective maladies.

Passing to the consideration of the principles which should guide us in the use of diet in disease I would lay stress again upon the importance of the personal factor. It is a wise plan always to ascertain what a patient's dietetic habits are before drawing up rules for him Nor must his likes and dislikes—or what may even seem his whims and fancies—be altogether neglected. Let us remember the shrewd saying of that great common-sense physician Sydenham, that "more importance is to be attached to the desires and feelings of the patient, provided they are not excessive, than to doubtful and fallacious rules of medical art." Though our rules are now, let us hope, less "doubtful and fallacious' than they were in Sydenham's time we can still not afford to neglect his counsel. Let us avoid, too, the offence of arbitrariness in our dietetic rules. By this I mean that one ought not to order or to forbid any article of diet without being able to give some good reason for doing so to ourselves if not to our patient. I remember a physician who had a very simple method of deciding what a patient should eat and avoid. He simply forbade everything the patient liked and ordered everything he disliked. I need hardly say that such is not the road to success in dietetic treatment.

Another great general principle which we must constantly bear in mind is what I may term the interdependence of the organs. They are "members one of another" and in prescribing a diet suitable to the needs of one organ the physician must never forget the requirements of others or of the body as a whole. I believe that neglect of this principle is one of the most prevalent errors in dietetic treatment. Nothing, for instance, is commoner than to find that a patient's diet has been ruthlessly cut down to spare his diseased stomach or kidneys until his general nutrition is brought so low that his last state is considerably worse than his first. Further examples of this we shall see immediately Lastly there remains the good rule never to make radical changes in diet abruptly. The scientific justification for this has been furnished by the recent researches of Pawlow, which show that the stomach acquires the "habit" of digesting any particular kind of food easily and secretes a gastric juice appropriate to it, and if the food is suddenly changed it takes the digestive organs a little time to adjust themselves to the new conditions and meantime the patient may suffer.

Coming closer to the subject and asking ourselves what is the value of diet in therapeutics it is well to recognise at the outset that many diseases cannot be influenced by this means at all. Change of diet is not a universal panacea any more than anything else. In enforcing this truth we must often run counter to the wishes of our patients, for nothing is commoner nowadays than for people to expect their medical adviser to draw up for them an elaborate scheme of what they should eat, drink, and avoid, no matter what their ailment may be, and to think that he has neglected his duty if he fails to meet their expectations in this respect. Now I think that there are only three great groups of diseases in which one can reasonably anticipate that dietetic means will be potent for cure. These are: (1) diseases of the organs (stomach and bowels) which prepare and elaborate the food; (2) diseases of metabolism (e.g., fever, obesity, malnutrition, diabetes, and gout) in which there exists a perversion of the usual methods of dealing with the nutritive constituents of the food by the cells; and (3) diseases of the excreto

cerned in

food. Let

should guide us in the dietetic treatment of some of these diseases.

As regards the dietetic treatment of dyspepsia—using the term in its widest sense—I would remark first of all that the mechanical form of the food must always be of more importance than its chemical composition. The reason for this is that disorders of the stomach are of comparatively little importance so long as its mechanical power of driving the food on into the duodenum is unimpaired. Now the ease with which this can be accomplished depends upon the mechanical resistance offered by the food to its conversion into chyme. The meals of the dyspeptic, therefore, must be small and must contain no ingredients which are difficult of solution. Cellulose in the vegetable foods and tough connective tissue in the animal are the things which it is of special importance to avoid. In further justification of this principle it may be observed that we do not yet know enough of the chemistry of the gastric juice or of its perversions in disease to enable us with any confidence to adjust the chemical composition of the food to the existing state of the gastric secretion. The only other general rule which I would lay down in dealing with dyspepsia is that it is important to distinguish between functional and organic diseases of the stomach. I know that these terms are open to criticism, but everyone here knows roughly what is meant by them. Amongst organic affections I would class cases of ulcer, carcinoma, catarrh, and dilatation, whilst the functional group—which, by the way, includes by far the larger number of the dyspeptics one meets with—embraces the "atonic" dyspepsias or cases of gastric neurasthenia and the functional disorders of secretion. Now from a dietetic point of view, the main distinction between the two groups is that whereas in the organic affections diet is everything, in the functional it is usually of subsidiary importance. One must be careful not to over-diet the functional cases, remembering the general principle already laid down that the requirements of one organ must not be met at the expense of the body as a whole. I saw the other day, for instance, a patient who had been kept for a long time on a fluid diet under the impression that he was suffering from malignant disease or gastric catarrh. He was much wasted and his bodily strength was greatly reduced. Under the use of a simple mixture and the encouragement to eat plenty of solid food he gained five pounds in weight in a few weeks with a proportionate improvement in all his symptoms. This was a case in which the nervous and blood-supply of the stomach, without which it cannot do its work, had been largely cut off by a diet which, with the best intentions, was designed to lessen the labours of the diseased organ. One is reminded in this connexion of the story of a young man who had lived not wisely but too well, and in consequence of his excesses suffered from serious dyspepsia. His medical adviser tried to induce him to follow a more temperate way of life and, failing in this attempt, sought to frighten him into obedience by telling him that the "coat of his stomach was entirely destroyed" "Well," replied the young man, "if his coat is destroyed the beggar has jolly well got to do his work in his shirt sleeves." That, gentleman, I believe to be the proper attitude to adopt towards the stomach in most cases of functional disorder. Treat it to a little wholesome neglect. In the dietetic treatment of disorders of the bowels, again, the mechanical condition of the food is the key to the situation. In diarrhœa one must select a diet which will leave as little unabsorbed residue as possible, whilst in cases of constipation the direct opposite should be our aim. Now the foods which leave least residue are weak decoctions of the cereals whilst vegetables and fruits leave most. When we are on this subject it might be of interest to discuss whether or not the view so often expressed is correct that the reason for the prevalence of constipation at the present day is the refinement of modern methods of preparing food. I cannot go farther into this branch of the subject just now, but my own feeling is that this theory is very far from being satisfactorily established. In recent years many authorities have advocated the treatment of neurasthenic conditions by a lacto-vegetarian diet, on the theory that such conditions are often set up and maintained by auto-intoxication from the intestine. I should be glad to know whether anyone here has had any experience of that method. Granted the correctness of the pathological theory the treatment is quite sound, for milk is undoubtedly the best intestinal antiseptic.

Of metabolic diseases we may first consider fevers. The time has long gone by when it was considered sound treatment to starve febrile patients and the modern plan seems to be to feed such cases up to the limit of their digestive capacity. It is questionable, indeed, whether the reaction has not gone too far and whether patients with acute fever are not in danger of being over-fed particularly by anxious friends and enthusiastic nurses. In chronic fevers, on the other hand, one can safely be liberal with diet and it is well in such cases to remember that fever does not in itself contra-indicate the administration of solid food if the patient has a desire for it. Local conditions of the alimentary canal, of course, may render this inadvisable, enteric fever being a case in point. Even here, however, I think it is quite possible to be too strict and we certainly want a more extended series of observations on the effects of solid food in that disease. In all forms of fever it is well to bear in mind the principle that carbohydrates should enter freely into the diet. Fats are disliked when the temperature is elevated and it has been shown that proteids not only fail to arrest the inevitable waste of nitrogenous tissues which fever entails but that their end products tend to increase still further the waste matters by which the blood is already flooded.

Obesity is a disorder of metabolism in which it is easy to over-estimate what diet can effect. One certainly sees cases in which one cannot fairly say that the total intake of food has been in any way excessive. I was consulted the other day, for example, by a man, aged 30 years, who had been growing steadily stouter since the age of 15, yet his diet had been quite moderate in amount. Such cases are hard to treat by mere restriction of food. They seem to depend on some deep-lying peculiarity of metabolism and one is tempted to suppose that in such cases the patient's body is really a more economical machine than normally or that there is an inborn tendency to form fat even at the expense of the other tissues. In the majority of cases in which we are consulted, however—those, mainly, which occur in the later period of middle life—the intake of total energy in the food is certainly beyond the needs of the tissues and where that is the case reduction of the food is the correct principle of treatment. Proteids, owing to the ease with which they are broken down, are little likely to cause harm and, indeed, a free supply of them is necessary if the patient's heart and muscles are to be maintained in vigour. The fats and carbohydrates, therefore, must be the object of our attack. Different "systems" of diet in obesity have been based on the degree to which each of these is respectively reduced but as far as the actual laying on of fat is concerned it is probably to a large extent a matter of indifference. As a rule, it is easier to restrict the carbohydrates because of the large proportion in which they enter into the diet of most people, but if the patient is a free fat-eater it may be advisable to restrict the fats as well. The question of fluids is also of less importance in the treatment of obesity than is commonly imagined. Experiment has shown that restriction of liquids does not appreciably affect metabolism, but if by forbidding a patient to drink with his meals we make it more difficult for him to get down an excess of food then of course such a restriction is justifiable. Alcoholic liquids, on the other hand, are always harmful to the obese, for alcohol is a potent sparer of fat. In the condition opposite to obesity—namely, malnutrition—our danger is that of ordering too one-sided a diet. The ease with which carbohydrates and fats can be stored up in the form of adipose tissue with a consequent increase in the patient's weight is apt to make us forget that to make a patient fat and to make him strong are not necessarily the same thing. Much of the fat put on in the Weir-Mitchell cures and in sanatoriums for consumptives is probably of little use to the patient and disappears rapidly when he returns to ordinary conditions of life. Of late, therefore, importance has rightly been attached to the advisability of a large use of proteid in the diet in cases of malnutrition. Proteid is a powerful cell stimulant and, as we have already seen, there is reason to suppose that if freely represented in the diet the resistance to disease is increased. Hence the value of meat to consumptives.

With the principles of diet in diabetes I may deal very briefly, for there is probably greater unanimity in this matter than in any other dietetic question. Everyone will agree that the object of treatment in this disease must be to remove sugar from the blood and all are aware of the importance of restricting the carbohydrates. It is apt, however, to be forgotten that to many diabetics of the severe type proteids are quite as harmful. Our great guiding principle, then, must be to insist upon a large consumption of fat, for that ingredient of the food alone is devoid of risk. In this disease, too, let us remember the general rule already laid down that the patient's nutrition must not be allowed to suffer in the mere attempt to remove his symptoms. In the severer cases, especially, the advice of the French statesman in another connexion should constantly be present to our minds: "*Surtout, pas trop de zèle!*" I think we would not be far wrong if we adopted it as a general rule that the milder a case of diabetes the more rigid should the restriction of diet be.

If diabetes is a disease about which our views are probably in a fair degree of harmony I fear the same cannot be said of gout. In no question of therapeutics, indeed, are there greater differences of opinion and practice than in the dietetic management of this disorder. One man forbids sugar, another alcohol, and another flesh foods, whilst yet another will put his patient on a diet consisting exclusively of lean meat and hot water. Let us see whether chemical pathology can afford us any guidance in this confusion. I suppose everyone will admit that uric acid is the *materies morbi* in gout and that our chief object must be to prevent its entering the blood. Now the uric acid of the body is derived from two sources. In part it is produced from certain chemical substances contained in the food (exogenous uric acid) and in part it is derived from the cells themselves (endogenous uric acid). The former of these can alone be controlled by diet. What, then, are the foods which yield no uric acid on assimilation? They are these: milk, eggs, vegetables (except asparagus and onions), fruits, and cereals (except oatmeal). On the other hand, all flesh foods, and particularly those which are rich in nuclein, such as the viscera (liver, kidneys, pancreas, and thymus), are fairly rich sources of uric acid and so also are the extractives of meat in all forms. Peas, beans, and lentils also yield uric acid and so does the caffeine contained in coffee and tea. The only strictly scientific diet for gout, then, is one from which all the articles just mentioned are excluded as has been especially insisted upon by Dr. A. Haig. On the other hand, there is the endogenous uric acid to reckon with and even although no uric acid producing substances are taken in with the food enough may still be produced in the body to give rise to gout. That is probably why dietetic means alone constantly fail to cure gout. The endogenous uric acid is the dark horse and in some cases there would appear to exist a vice of metabolism which causes it to be produced in undue amount or which renders its further oxidation impossible. These are the patients who continue to suffer though their diet is as spare as that of a Trappist monk. The question is sometimes asked: Why is it, if flesh yields uric acid, that a diet of lean meat and water suits some gouty subjects so well? The explanation of this apparent paradox I believe to be that such a diet is free from proteid-sparers. So long as these are absent the oxidation of the proteid is so complete that little uric acid is left over.

We come, lastly, to the principles which should guide us in the dietetic treatment of renal disease. Here I would draw a sharp distinction between acute and chronic cases. In acute nephritis, especially so long as blood is present in the urine, an exclusively milk diet is, by common consent, that which gives the best results. Although clinical experience is quite conclusive on this point the scientific explanation of the advantages of milk is not yet forthcoming. To some extent, of course, it acts as a diuretic and it has the advantage of being free from those extractive matters which meat contains and which appear to be irritating to the kidney. The fact already alluded to, that milk is an intestinal antiseptic, may also help to explain its suitability, for under its use products of putrefaction such as the ethereal sulphates which are normally absorbed from the bowel and excreted by the kidney are greatly lessened In chronic nephritis affairs are more complicated I was consulted only last week by two patients who illustrate a couple of fallacies which are current about the dietetics of that disease Both were men beyond middle life suffering from granular kidney One of them had been told to eat no meat but to drink milk instead, the other had, on the advice of friends, adopted a diet from which the "red meats" were excluded but which contained chicken and fish In both instances, I submit, the diet was incorrect, but the error was much graver in the former case than in the latter In the case of the first patient the general principle on which I have already laid stress had been neglected—namely, that one should never arrange a diet suited to the requirements of one organ to the neglect of the others Now a patient with chronic renal disease must maintain a vigorous heart, for if his heart fails his blood pressure falls, his urine becomes scanty, and he is apt to pass into uræmia But a vigorous heart cannot be maintained on milk alone and, as a matter of fact, in the former of these patients cardiac failure was beginning Hence it is that in chronic renal disease meat must not be altogether abolished from the diet, although foods which contain only the extractives of meat without its albuminous elements should be rigorously avoided I am aware that animal food tends to send up the blood pressure and in cases where the arterial tension is high it often requires fine steering to avoid the risk of an apoplexy on the one hand or cardiac failure and uræmia on the other—but the latter risk is quite as great as the former, although it is so much oftener forgotten But what was the fallacy in the case of the patient who ate white meats but not red? Well it has recently been shown by van Noorden and his pupils that the white meats are as rich in extractives as red, so that the substitution of the former for the latter in the diet, though harmless, is also devoid of advantage Whilst I am on the subject of fallacies in the treatment of chronic renal disease let me take occasion to indicate another It is commonly said that even in cases of chronic nephritis in which there is a considerable amount of dropsy, as, for example, in large white kidney, one should allow the patient *to drink plenty of liquid in order to promote elimination* Now it has recently been shown by careful clinical observation that this idea is groundless Restriction of fluids in such cases not only does not interfere with excretion but has the advantage of helping to remove dropsy One need have no hesitation, therefore, in recommending a dry diet to such patients

Now, gentlemen, I have come to an end I have been obliged to exclude many important subjects from this hurried survey, but I have tried to set up as many pegs as possible on which to hang discussion In particular I regret that I have been unable to refer at all to the important question of beverages Might I, in closing, venture to suggest that on some future occasion the society should hold a discussion on what, if I may coin a much-needed word, I would call the principles of "bibetics"?

THE DRAINAGE OF THE KNEE-JOINT IN ACUTE SUPPURATIVE ARTHRITIS[1]

BY HAROLD L BARNARD, M S LOND, F R C S ENG,

ASSISTANT SURGEON TO THE LONDON HOSPITAL

AN acute pyogenic infection of the knee joint is one of the most dangerous of suppurative diseases and one of the most unsatisfactory class of cases that a surgeon can be called upon to treat Other collections of pus in the body can be efficiently and reliably drained and are attacked by the surgeon with confidence, but when the knee joint is filled with pus a feeling of helplessness and futility appears to overshadow the treatment The results only too well justify this feeling Many of these cases of suppurative arthritis occur in hospital and follow wiring of patellæ or removal of semilunar cartilages or foreign bodies They are under constant medical supervision and therefore they are recognised early They receive prompt attention and are afterwards treated with all the resources at the command of the surgeon who has had this unfortunate accident, yet what are the results? Many deaths, more amputations, and the rest of the patients after months of suppuration leave the hospital in broken health with the knee ankylosed and often open sinuses

The method usually adopted to drain the knee joint is to make lateral incisions two or three inches long on either side of the patella and to pass tubes from these across the joint and up into the subcrureus bursa The joint is then irrigated with some antiseptic solution such as carbolic lotion (1 in 40) or perchloride of mercury (1 in 1000) The leg is then placed on a back splint and surrounded with copious fomentations or dry dressings

Mr Jacobson in his "Operative Surgery," when speaking of draining the knee joint after wiring the patella, says that, should it be decided to do so, "drainage should be employed through the wound to the most dependent part of the joint at the outer side (Lister), thrusting the instrument here through the joint and soft parts, cutting upon it and drawing a drain through" It was an attempt and a failure to do this in a case of suppurative arthritis which induced me to carry out this investigation of the anatomy of the knee joint and which led me to plan the posterior incisions recommended in this paper

In 1888 Sir Frederick Treves advocated in the *British Medical Journal* of July 7th continued irrigation in such cases with some weak antiseptic By blocking the outlet tube the joint was distended with the fluid once or twice a day He published two most hopeful cases in which good movement was obtained after the treatment. Quite recently one of Sir Frederick Treves's patients came to my out-patient department at the London Hospital for some other matter His knee had practically perfect movement Unfortunately the treatment has not led to similar results in a series of cases under several surgeons at the London Hospital There have been seven cases in the last ten years treated by this method Two of the patients died from pyæmia, four had fibrous ankylosis after many weeks in hospital One patient [illegible] open sinuses In only [illegible] ie value of any treatment [illegible] to really bad cases of [illegible] afraid that the very hopeful results of continued irrigation are further militated against by the fact that the first two cases reported appear to have been mild ones The first had been opened for chronic synovitis and drained After a week or so the knee became infected apparently when the tubes were removed They were at once replaced and the knee was more thoroughly drained Continued irrigation was established a few days later This joint, which was being drained even before it was infected, can hardly be considered on a par with the cases of punctured wound where for some days the pus is retained in the joint under high pressure and no doubt with increasing virulence The second case followed a fall without a wound and the temperature was only 101° F

Many years ago, when I was a dresser, a case of suppurative arthritis of the knee joint in a child was treated in the London Hospital first with ordinary lateral drainage and then with continued irrigation, but, as both these measures failed to drain the joint efficiently and the temperature continued to range at a high level, the surgeon in charge laid open the knee joint by a curved incision across the front of it and divided the patella and fully flexed the knee, so that all parts were fully exposed The result was satisfactory

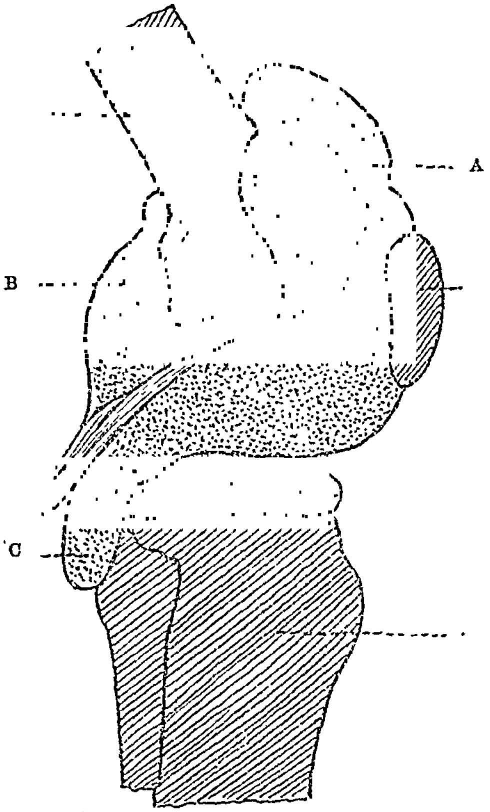
Mr Walter Whitehead has recently reported a favourable case in the *British Medical Journal* The knee was infected whilst a loose cartilage was being removed Free drainage and *irrigation were adopted but failed.* The patient was delirious, his temperature was 103° F, and he was in a state of extreme exhaustion His knee was then laid freely open by a transverse incision, the patella was sawn across, and the crucial ligaments were divided The joint was packed with gauze after it had been thoroughly cleaned. The patient rapidly convalesced and in 15 days the granulating surfaces of the joint were placed in an extended position. He made a good recovery with a stiff but straight leg This method is no doubt efficient in all cases in which the pus has not burst through the capsule behind and is already tracking up and down the leg But it is heroic and in every case in which it is applied all hope of a mobile joint is necessarily relinquished The leg is moreover greatly damaged by the *free division* of the quadriceps insertion and other muscles sending expansions to the capsule of the joint In short, it should be, as indeed it is, a forlorn hope of conservative surgery when amputation is refused or when the surgeon still hopes against hope to save a limb for the condition of which he is responsible.

---

[1] A paper read before the Clinical Society of London on Feb 13th 1903

It was this gloomy experience of the general failure of the present methods for draining the knee-joint which induced me to investigate the anatomy of this serous cavity in order to discover why it was so difficult to drain it, and whether incisions could not be planned which should make the retention of pus within the cavity of the joint impossible.

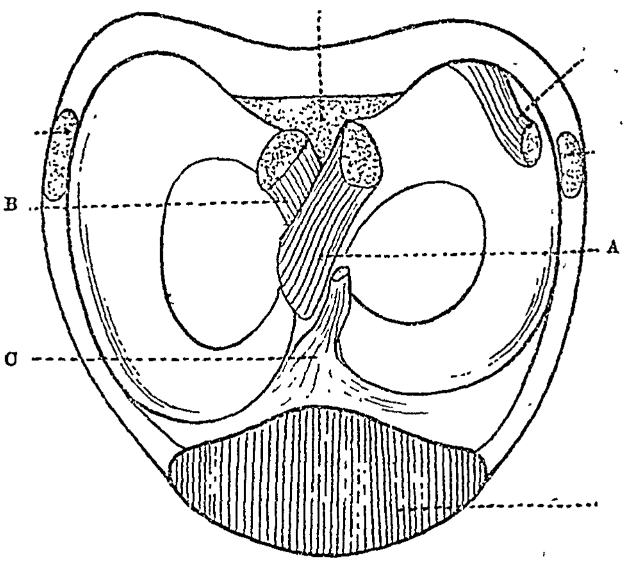
Fig. 1.



Longitudinal section through knee-joint.

This figure of the complicated synovial membrane of the knee-joint is taken from Testut's Anatomy. The great subcrureus bursa (Fig. 1, A) is well known and where the joint is drained it is never overlooked; but this is not the case with the complicated pouches at the back of the joint. The knee-joint is divided into two main pouches behind by a septum projecting forward from its posterior wall and formed in order from behind by the posterior ligament, the crucial ligaments, and the ligamentum mucosum (Fig. 2). Each of these pouches receives the posterior protuberant extremity of the corresponding condyle in extension. These pouches terminate above and behind the condyles in sacs which are beneath the corresponding head of the gastrocnemius (Fig. 1, B). The outer pouch also sends a synovial prolongation along the popliteus tendon (Fig. 1, C). The usual method of draining the knee-joint by a tube passed below the patella and another passing up into the subcrureus bursa leaves these two posterior pouches untouched. The leg in such cases is kept extended on a splint, which closes the way to the front of the joint by a coaptation of the bony surfaces. When these pouches rupture from distension with pus their anatomical position directs the pus up to the thigh between the hamstring and the great adductor and down the calf between the gastrocnemius and the deep muscles. It is difficult, if not impossible, to drain both these collections of pus at once. For if the leg be elevated the lower will drain but the upper will not, and *vice versâ* if the leg be lowered. It is clear, then, that each of these posterior pouches must be drained by an incision placed as far back as possible. On the inner side, the knee being fully extended, the protuberant extremity of the condyle is cut down upon and a pair of stout forceps are pushed under the head of the gastrocnemius and withdrawn open. A tube is then inserted. This is more easily done if the knee be flexed as the tube is put in, since this relaxes the head of the gastrocnemius and the posterior ligament. This incision will be found to be between the sartorius and gracilis tendons and usually just behind the internal saphenous nerve.

Fig. 2.



Transverse section through knee-joint. A, B, crucial ligaments. C, ligamentum mucosum.

In a similar way the outer condyle is cut upon. The incision here passes between the biceps tendon and gastrocnemius and just behind the external popliteal nerve. It is important, therefore, in both cases to be careful in the use of the knife and to see that the incision is in the line of these nerves. When the skin has been incised it is easy to scrape down to the capsule with some blunt instrument. The knife can then once more be safely used to open the joint freely. Anatomical guides are useless in practice because of the inflammatory swelling; one knows that the pouch surrounds the prominent condyle, which can easily be felt, and one cuts down until the cartilage of the condyle is reached. A drainage-tube should be passed across the front of the joint beneath the patella and another should be directed up into the subcrureus bursa from either the inner or the outer side. This tube can with advantage be brought out through a median incision at the highest point of the joint anteriorly. The discharge from the anterior tubes rapidly diminishes and the wounds heal some time before the two posterior incisions cease to discharge and close. This is proof in itself that the drainage is practically as well as theoretically correct.

I have treated nine cases by this method, and in all the temperature reached normal in a day or two, appearing to show that no pus remained in the joint under tension. The evacuation of the pus was greatly assisted in several cases by gentle stroking massage of the subcrureus bursa from above and of the popliteus bursa from below, movements which can be simultaneously carried out. As soon as the temperature is normal I would recommend massage and passive movement. These must be carried out by a thoroughly efficient masseuse. The method is the same as for fractured patella and is directed to similar ends. The patella is firmly grasped and moved about on the condyles of the femur, so that it may not form adhesions to it. The knee is then steadily lifted from the bed so as passively to flex the knee-joint.

We have so far seen that anatomy indicates the presence of those large pouches behind the knee and that they can easily and effectually be opened and drained. It only remains to narrate a typical case of acute suppuration which I had an opportunity of seeing some time ago, in which this was not done, and these pouches ruptured and apparently involved the popliteal vein, leading to pyæmia. An old and somewhat alcoholic man fractured his patella. After an interval of about a week the fragments were wired together. Unfortunately, the knee became septic about the third day. The knee was opened by the usual anterior incisions and continued irrigation was instituted. In about a week the patient died. At the necropsy pus was found in the depths of the popliteal space tracking down into the calf around the vessels and up the back of the thigh The lungs were studded with pyæmic abscesses. Before narrating the nine cases I have treated in this way I should like to say that they were consecutive The first four were traumatic cases and have done much better than the last five which were cases of auto infection.

CASE 1 *Wound of the right knee joint with a rusty hat pin, suppurative arthritis, drainage by anterior and posterior incisions, rapid recovery*—This case was under the care of Mr C W Mansell Moullin who kindly gave me permission to use it The patient, a little girl, aged eight years, was admitted to the London Hospital on Jan 18th, 1901 Seven days before admission she ran a rusty hat pin into her right knee The hat pin was extracted by her medical attendant and the wound healed. On admission the right knee was red, hot, swollen, and œdematous and tightly distended with fluid which an exploring needle proved to be pus Her temperature was 103° F and her pulse was 110 Her general condition was bad and she suffered great pain in her knee On the same day Mr Hugh Lett, who was house surgeon to the case, operated by the posterior incisions recommended in this paper in addition to the usual anterior ones Pus under high tension spurted from the incision on the inner condyle The progress of the case was satisfactory The temperature fell to 99 5° in three days and reached normal in six days The tubes were removed in 14 days

It is very interesting to note in this case that the anterior incisions closed some time before the posterior ones, a fact which seems to indicate that a posterior drain is right in practice as well as in theory She can run and walk well and her knee can be flexed nearly to a right angle

CASE 2 *Suppurative arthritis of the left knee joint following lymphangitis and incisions, drainage by posterior incisions*—A boy, aged 15 years, was admitted to the London Hospital on March 7th, 1901 One month before admission he contracted a sore upon his foot from the rubbing of his boot Lymphangitis spread up his leg and led to an abscess over the lower part of the tibia and another over the internal condyle of the femur These abscesses were opened by a general practitioner On admission to the hospital the lad had a sinus in the lower third of his left leg and another on the inner side of his knee, which entered the popliteal space The knee was flexed somewhat and contracted The temperature was normal Two days after admission the house surgeon straightened the knee under an anæsthetic and thoroughly opened up and drained a large collection of pus lying in the depths of the space near the knee joint On the next day the knee became distended with fluid and very tender The temperature rose to 103° F and on the following day it was 104° On March 11th I opened up the knee joint by five incisions Two were placed on either side of the patella and a tube was passed across the front of the knee joint One passed through the quadriceps into the upper extremity of the subcrureus pouch and a tube was passed from this incision out of the inner lateral incision Each condyle was cut on to in turn from behind and a tube was inserted As the joint was opened by the inner incision pus gushed out The temperature fell from 104° to 99° in 36 hours and the leg became much less swollen and painful It was some time before the sinuses closed but the temperature did not again become raised above normal for 24 hours

I have, unfortunately, not been able to trace this boy and therefore cannot give his ultimate condition which promised to be good

CASE 3 *Compound fracture of the patella, suture, suppuration, drainage, recovery with good movement*—This case has already been fully reported in the Transactions of the Clinical Society The chief points are these The patient was caught by an engine in August, 1900 whilst crossing the track, and struck upon his patella so that this bone was crushed and the lower fragment projected from the wound The parts were freely exposed and thoroughly washed and the more ragged tissues were cut away finally, the fragments were brought together by a kangaroo tendon after Stimson s method. For seven days the case did well then cellulitis commenced, and in the course of the next two months much of the subcutaneous tissues round the knee sloughed away The knee-joint became swollen and very tender It was therefore opened on either side of the patella and behind in the manner advocated in this paper His knee was very slow to heal but recovery was hastened by massage and passive movements

The ultimate result was much better than could have been anticipated The patella was united by bone and the knee joint could be flexed to a right angle He could walk and run practically without a limp It must be admitted, however, that this was a mild infection The result is practically perfect as regards his knee, although he still appears to be suffering from traumatic neurasthenia

CASE 4 *Wound of the right knee joint with glass, suppurative arthritis, drainage*—A boy, aged 14 years, was admitted under my care into the London Hospital on March 23rd, 1902 Ten days previously he fell on a piece of glass, wounding his right knee, which had been swollen ever since but he was able to walk until two days before, when it became exceedingly painful and swollen. On admission the knee presented all the signs of suppurative arthritis His temperature ranged from 103° to 104° F His general condition was good, but he had a tendency to be delirious at night Operation was performed on the day of admission, the knee joint being laid open front and back and drained with tubes The drainage was not strikingly efficient in this case The temperature slowly declined but did not actually reach normal The change for the better really occurred in his case when Mrs Palmer, masseuse to the London Hospital, began to massage the joint and to produce passive movement She found that gentle stroking movements in front from above down towards the patella evacuated large quantities of pus and that a similar result followed upward massage of the calf behind Apparently the pus was bagging in these two situations where, as we have seen, deep pouches of the knee joint exist.

The joint promised to have some movement when the patient left the hospital, but he fell soon after and wrenched it, and since then it has been quite stiff and flexed I propose to take him into the hospital, to straighten his knee, and to give him a poroplastic splint to prevent recontracture.

CASE 5 *Suppurative arthritis of the left knee probably due to leucorrhœa, drainage, persistent sinuses*—A married woman, aged 23 years, was admitted to the London Hospital on July 18th, 1902 Three days previously her left knee had become swollen and painful Her temperature was 100° F She was three months pregnant No cause could be found for the suppuration except a leucorrhœal discharge A needle was inserted into the knee joint and pus was withdrawn which, although sent to the bacteriological department, was apparently lost The joint was then drained and irrigated with biniodide of mercury solution in a manner exactly similar to previous cases For ten days after the operation the temperature remained absolutely normal The tubes were then removed and the temperature began to oscillate The tubes were replaced and several subsequent attempts were made to remove the tubes, but on each attempt the joint again became distended with pus and they had to be replaced At a subsequent operation bare bone was found extending some distance down the back of the tibia and it seems probable that the mischief in the knee had originated in the head of the tibia

When last seen the sinuses were still open. The temperature was normal, but the synovial membrane was greatly thickened and pulpy and closely resembled that of a tuberculous joint I propose thoroughly to lay open this knee joint at an early date and to deal with whatever condition may be encountered.

CASE 6 *Purulent synovitis of the right knee joint apparently due to a leucorrhœal discharge in a woman, aged 65 years, drainage, temperature normal next day, later amputation for persistent sinuses and painful joint*—The patient, an elderly female, was admitted to the London Hospital under the care of Mr Jonathan Hutchinson jun whilst I was his substitute Six days before admission she was seized with severe pain in the right knee which became hot and swollen She had several rigors *No cause was given for this condition* except that it might have been produced by kneeling whilst scrubbing floors She had suffered from leucorrhœa for several weeks On admission her general condition was very bad indeed, she was in a typhoid condition Her tongue was dry and brown and her lips were covered with sordes Her temperature was 102° F The right knee was tense tender, hot painful, and red. The exploring needle withdrew thick pus The knee was freely laid open and drained by four incisions one on either side of the patella, from the inner one of which a tube passed up into the subcrureus pouch and another across the joint below the patella. The two posterior pouches were laid open and tubes were passed in through the incisions whilst the knee was flexed, which, it was found, relaxed the structures and enabled the tubes easily to be placed in a good position. The temperature fell to normal on the next day and her general condition rapidly improved. Her subsequent progress was not, however, satisfactory. For a fortnight her temperature oscillated each night from normal to a degree or two above, but when upward massage over the calf was begun it remained normal. This procedure evacuated a considerable quantity of pus from a deep pouch which was probably the popliteus bursa as in Case 8.

When Mr. Hutchinson returned to the hospital about two months after the operation, although the temperature remained practically normal, the knee was exceedingly painful and the poor old woman showed the feeblest signs of repair. All the sinuses were open, although the discharge from the anterior ones had practically ceased. Mr. Hutchinson therefore amputated the leg in the lower third of the thigh. She made a rapid recovery.

CASE 7. *Tuberculous epiphysitis of the lower epiphysis of the femur; incised by a general practitioner; erysipelas; infection of the knee joint; drainage; recurrent attacks of erysipelas; amputation.*—A small ill-nourished boy, aged three years, was admitted to the London Hospital on July 28th, 1902. The history was that seven weeks previously a painless swelling had appeared over the inner condyle of his right femur. This was incised by the family medical attendant who plugged it with gauze and fomented it. 14 days before admission he became feverish and delirious and a red mottled swelling started from the wound and spread up and down his leg; soon after his knee-joint became distended and painful. On admission a sinus was found on the inner side of the right knee which led down to carious bone. The popliteal space was greatly swollen and contained much pus. The knee was obviously the seat of suppurative arthritis. It was drained and irrigated in the manner advocated in this paper and in five days the temperature reached normal and remained there except during a relapse of erysipelas. The patient did not, however, do well. The sinuses remained open and after a serious attempt to remove all the diseased bone from the carious focus in the end of the femur which failed, but which apparently lighted up the septic mischief once more, the leg was amputated in the middle of the femur.

The specimen is shown here. It will be seen that the joint cavity is obliterated by fibrous tissue and the result at the best could only have been fibrous ankylosis. In the lower femoral epiphyseal line in the situation previously occupied by the internal condyle is a carious cavity filled with purulent tuberculous material which formed the primary focus of the whole trouble.

CASE 8. *Acute pneumococcal arthritis of the right knee-joint; drainage.*—This case was under the care of Mr. H. P. Dean who has kindly allowed me to use it. I was substitute for him at the time. A boy, aged 14 years, was admitted to the London Hospital on July 30th, 1902. A month previously he had suffered from influenza from which he was convalescing when seven days before admission he was seized with severe pain and swelling in the right knee which became progressively worse. There had been no accident. On admission the boy's condition was very bad. He was emaciated, his temperature was 104° F., and his pulse was rapid and feeble. The lungs gave no signs of existing disease. His spleen was not enlarged or tender. The whole of his right leg from the lower third of the thigh to the toes was tremendously swollen, red, and œdematous, so that it was at first a matter of doubt whether the case was one of acute periostitis of the tibia with pus spreading up and down the limb or distension of the knee-joint with pus which had extended beyond the capsule behind and involved the popliteal vein and lymphatics. The characteristic position of the knee-joint in semi-flexion with well-marked fluctuation decided the point. A medium-sized trocar passed under the patella failed to evacuate pus but as it was withdrawn a gelatinous cord of pus followed it. The knee-joint was then laid open by anterior and posterior incisions. The cavity of the joint was full of clots which so closely resembled those seen in pneumococcal empyemata that a diagnosis of pneumococcal arthritis was at once made. The report of Dr. William Bulloch, bacteriologist to the London Hospital, was as follows: "Films show no organisms. Culture shows slight growth of cocci in short chains, most probably pneumococcus." The temperature reached normal on the fifth day, but continued to oscillate to about 100° each night until the fourteenth day, when Mr. Dean, who had returned from his holiday, explored the back of the knee-joint, divided some part of the posterior ligament of the knee-joint, and evacuated a pocket of pus tracking down the back of the tibia apparently in connexion with the popliteus bursa. The temperature then ceased to oscillate and the boy rapidly recovered.

I think there is very little doubt that at the time of the first operation the popliteal pouch of the joint had already ruptured and that the popliteal vessels were pressed upon. This would account for the great œdema of the leg and foot which rapidly subsided after the first operation and such a collection of pus, although ill-drained, was certainly found 14 days later.

CASE 9. *Acute suppurative arthritis of the knee-joint occurring in the course of whooping-cough; posterior drainage.*—A little boy, aged five years, was admitted under my care into the London Hospital on August 27th, 1902. For five months he had been suffering from whooping-cough which he still had. Two days before admission he fell, striking his knee but producing no wound or abrasion. He had not walked since the accident. On admission the condition of the child was very serious. His temperature was 103° F., his pulse was rapid and feeble, and he was quite delirious. The knee was distended with pus and was red, hot, and œdematous. The pus removed by the exploring needle was examined by Dr. Bulloch and found to contain a pure culture of streptococci. The knee-joint was freely drained on the day of admission in the manner advocated. The temperature was normal in four days but suppuration continued for three weeks. The tubes were removed 25 days after operation. His recovery was unfortunately delayed by two attacks of erysipelas, but ultimately he was sent away to the country where his sinuses rapidly healed.

He now has slight movement of his knee-joint which I hope persistent massage may improve.

Some of the cases in this series are not, I admit, very happy ones, but they are, as I have said, consecutive. The four traumatic infections which are usually regarded as so much worse did very well. Two patients had good movement and one had some movement when he left hospital. The other has fibrous ankylosis. The five cases of blood infection were most unsatisfactory in their progress. Two patients had the leg amputated but it will be seen that one was an old woman, 65 years of age, in whom though her temperature had been reduced for weeks, the sinuses seemed unable to heal. The other case was one of tuberculous abscess in the end of the femur which became infected with erysipelas and invaded the joint.

The earlier traumatic cases had led me to hope that if the infected joint were taken in time and efficiently drained behind as well as in front, we might confidently count on obtaining a mobile joint, but subsequent cases, more especially those due to auto-infection, have made me less sanguine.

I am still confident that this method of efficient drainage will cope successfully with the immediate dangers of sepsis, septicæmia, pyæmia, and the formation of large abscesses burrowing up and down the leg, for in no case did the temperature fail to reach normal in a few days. It is, however, clear that the subsequent progress of the cases, whether suppuration becomes chronic and sinuses persist or whether the cartilages are destroyed and fibrous ankylosis follows, depends mainly on the cause of the suppuration. We can scarcely hope to save the leg if the disease originates from a focus in the femur or tibia. The two most unsatisfactory cases of all arose apparently from a leucorrhœal discharge. I very much regret that no bacteriological report is forthcoming in either case.

In conclusion, I would advise that all really acute cases of suppuration in the knee-joint, say with a temperature ranging from 103° to 104° F., should be treated by anterior and posterior incisions, more especially if they arise from punctured wounds. When the suppuration arises from auto-infection and is subacute, with a temperature of not more than 102°, I should be inclined—taught by the cases recorded above—first to make lateral incisions on either side of the patella and to wash out the joint thoroughly and to drain it. The joint must be treated as though it were an aseptic case, for in auto-infection we have usually to deal with one micro-organism only, and that often a mild one. We must therefore beware lest in casting out one micro-organism we admit several others worse than the first. Should this partial drainage fail to bring the temperature down in a day or two the posterior pouches should be laid open and thoroughly drained.

Wimpole street, W.

INVAGINATION OF MECKEL'S DIVERTICULUM.[1]

BY J. F. DOBSON, M.S. LOND., F.R.C.S. ENG.

ON July 29th, 1902, I saw with Dr. F. J. Coleman of Leeds a little boy, aged four and a half years, who had been suffering for 36 hours from acute abdominal pain accompanied by vomiting and the passage of blood and mucus from the bowel. A swelling had appeared in the right iliac region and a diagnosis of intussusception had been made. When I saw him there had been no vomiting for several hours, but he was in constant pain; the pulse was 120 and the temperature was normal. A soft moveable tender swelling was detected in the right iliac region extending upwards to the right costal margin, which was undoubtedly an intussusception. He was removed to a surgical home and an operation was performed the same evening.

Chloroform was administered and the abdomen was opened by an oblique incision over the tumour, the muscular fibres being separated without division. The peritoneum was opened, a quantity of serous fluid escaping, and the tumour was withdrawn from the abdomen. It was found to be an intussusception of the ileo-colic variety and was reduced without much difficulty until the apex was reached. A pedunculated swelling was then found projecting into the interior of the intestine and forming the apex of the intussusceptum. This swelling was evidently an invaginated Meckel's diverticulum, as shown by the dimpling of the peritoneal surface of the gut and the presence of a small mesentery which disappeared into this dimple. An attempt was made to reduce this invagination by pressure, but the surrounding intestine was in an extremely bad condition and tears began to appear in the peritoneal coat. It was evident that the invagination could not be reduced. The loop of bowel implicated was emptied by pressure and tied off with a piece of rubber tubing. The tumour and surrounding portion of bowel were then resected with scissors. The section did not completely divide the loop of intestine, its continuity being maintained by a narrow strip at the attachment of the mesentery. There was a great difference between the intestine above and the intestine below the seat of resection. Below, the intestine was distended to twice the size of the intestine above; its walls were much thickened and infiltrated; there were extravasations of blood under the serous coat and necrotic patches in the mucous membrane. Above, the intestine was almost normal in appearance, empty, and contracted. It was rather doubtful whether sutures would hold in the wall of the intestine below, but the patient was in such a bad condition that it was impossible to resect more intestine. A small Mayo Robson's bobbin was inserted into the intestine and continuity was restored by two layers of continuous sutures over the bobbin, an inner suture of fine catgut passing through all the coats and an outer suture of fine silk passing Lembert fashion through the serous and muscular coats. The loop of intestine was placed immediately beneath the abdominal incision, the omentum was so arranged as to isolate it from the general peritoneum as far as possible, and a small drainage-tube was passed in through the middle of the wound, which was then closed by three layers of sutures. There was a copious discharge of serum through the drainage-tube during the first 24 hours. The patient passed a restless night, the pulse gradually increasing in frequency; [illegible] me extremely ill, the pulse ro[illegible] dying. One and a half pint [illegible] infused into the right median basilic vein, large doses of liquor strychninæ were given hypodermically, and the lower bowel was washed out. A copious evacuation of extremely offensive bloody fluid resulted and the patient immediately began to improve, the pulse-rate falling within half an hour from 200 to 130. On the following morning the pulse was 120 but the temperature had risen to 103° F. There was some general distension of the abdomen and he complained of considerable pain in the region of the wound, but there was no vomiting. The discharge from the drainage-tube became purulent and rather offensive; evidently there was some peritonitis around the sutured intestine which was no doubt due to infection from the interior of the bowel at the time of operation. The bowels were moved by turpentine enemata and the disten[illegible] the drainage-tube rapidl[illegible] and he was able to tak[illegible] any discharge of fæc[illegible] August 9th the wound was entirely healed with the exception of a small granulating area at the site of the drainage-tube, the patient was taking light food very well, and the bowels were acting regularly. At present the child is in excellent health

In the first edition of his work on Intestinal Obstruction Treves mentions a specimen of an invaginated Meckel's diverticulum in the Guy's Hospital Museum which he says is "probably unique." The invaginated diverticulum had given rise to a fatal intussusception. In the second edition of the same work is figured a specimen[2] from the Museum of the Royal College of Surgeons of England consisting of an invaginated Meckel's diverticulum which had led to a fatal intussusception. The Museum of St. Bartholomew's Hospital contains two similar specimens, one from Adams's case[3] and one reported by Willett.[4] In both cases the specimens were obtained post mortem. Boldt[5] at a meeting of the New York Pathological Society showed another similar specimen. Cases have also been reported by O'Conor,[6] Adams,[7] Betham Robinson,[8] Pitts,[9] Eve,[10] Erdmann,[11] Ewald,[12] Weil and Frankel,[13] Hohlbeck,[14] Kuttner,[15] Stubenrauch,[16] Wainwright,[17] and Travers[18]—in all, 13 cases. Of these 13 cases four recovered—O'Conor's, Pitts's, Wainwright's, and Travers's cases. In O'Conor's case a slough of intestine with an inverted diverticulum was passed on the ninth day. In Wainwright's case the intussusception and the invaginated diverticulum were easily reduced, the diverticulum was clamped and cut away, and the opening in the intestine was closed by Lembert sutures. In Pitts's case the intussusception was reduced easily by pressure, and the invaginated diverticulum by the finger introduced through an incision in the bowel. In Travers's case the intussusception was reduced and the invaginated diverticulum was partially reduced, recovery ensuing.

Of the nine fatal cases in two no operation was performed and the condition was discovered post mortem; in two an artificial anus was established; and in five enterectomy was performed, followed by primary enterorrhaphy. It is noticeable that every case in which the invaginated diverticulum could not be reduced terminated fatally, with the exception of the one in which recovery followed the [illegible] Also with one exception— [illegible] diverticulum was resected [illegible] as uniformly unsuccessful. [illegible]nvagination of a Meckel's diverticulum may occur with or without an invagination of the ileum. Heller,[20] indeed, found one which hung free in the lumen of the gut without causing any disturbance. Apparently in the majority of cases the invaginated diverticulum leads first to an enteric and then to an ileo-colic intussusception. In Hohlbeck's case the mucous membrane only of the diverticulum was inverted and this had given rise to an enteric intussusception.

[10] Ibid.

The mechanism of the production of the invagination is probably as follows: some irritant body enters the lumen of the diverticulum and gives rise to spasmodic contraction of the muscular walls. In the efforts to expel the irritant material the apex of the diverticulum becomes caught in the grasp of the circular muscle and is drawn into the lumen of the intestine; invagination of the rest of the diverticulum then follows. Once inverted into the intestine the diverticulum acts in the same way as a polypus may do, and gives rise to an intussusception. To permit the occurrence of invagination it is essential that the apex of the diverticulum be free and not attached by ligament or adhesion to the umbilicus, to the mesentery, or to neighbouring coils of intestine. It is evident that any case of intussusception is very gravely complicated by the presence of an invaginated Meckel's diverticulum, the danger consisting in the rapidity with which the invagination becomes irreducible. In some cases reduction has been possible, but in the majority, even when the intussuscepted ileum could be easily reduced, the invaginated diverticulum could not. This difficulty is due partly to the narrowness of the lumen of the diverticulum and partly to the fact that being at the apex of the intussusceptum its walls become rapidly œdematous and infiltrated with blood. It is impossible to diagnose the condition beforehand and one may find in any case of intussusception, even when the operation is performed at an early stage, an irreducible diverticulum which must be excised. When the diverticulum can be reduced it may be left, though in view of possible after-consequences, such as recurrence of the invagination, adhesion and intestinal strangulation, perforation, &c., it would be better to remove it. It is, of course, impossible to leave an irreducible diverticulum projecting into the interior of the intestine; recurrence of the intussusception is almost certain to take place, and in any case it is sufficiently bulky to obstruct the passage of intestinal contents. The diverticulum may be removed by a lozenge-shaped incision in the long axis of the gut which is subsequently closed in the transverse direction, or by cutting out the portion of intestine to which the diverticulum is attached.

It is difficult to say whether after resection of the diverticulum primary enterorrhaphy should be performed or an artificial anus established; both operations have been attended with a frightful mortality in cases of intussusception. The mere difference between suturing the ends of the intestine together and suturing them to the skin cannot in reality have any influence on the mortality; one operation is as easy as the other and can be as rapidly performed. The point to be considered in choosing between the two operations is by which method can the poisonous contents of the intestine be most rapidly and completely removed. If the intestines above the seat of resection are full and distended with decomposing fluid it would appear to be safer to establish an artificial anus. In the case under review the intestines above were collapsed and there had evidently not been complete obstruction; for that reason a primary enterorrhaphy was performed. It became evident during the first 12 hours after the operation that although the small intestines above the intussusception were empty and collapsed the intestine below had been full of decomposing bloody fluid and this gave rise to a profound and almost fatal toxæmia. It is doubtful whether this poisonous material could have been removed by forming an artificial anus at the seat of resection. In a similar case possibly it would be advantageous to drain the cæcum by a small Paul's tube and also to inject a saline aperient into the bowel as recommended by Marmaduke Sheild. It is a wise precaution to adopt drainage of the peritoneum in all cases in which plastic operations are performed on the intestines during an attack of acute obstruction as the virulence of the intestinal bacteria is at such times much enhanced; it is impossible to prevent some fouling of the peritoneum and a more or less severe attack of peritonitis may follow the operation. Somewhat allied to these cases are invaginations of the vermiform appendix which may give rise to a cæcal intussusception. Monsarrat[21] in reporting such a case suggests the use of the term "appendico-cæcal" to describe this variety of intussusception. The term "diverticulo-enteric" would be suitable as a designation of the form of intussusception produced by the invagination of a Meckel's diverticulum.

Leeds.

NOTES OF A CASE OF EXTIRPATION OF A TUMOUR OF THE PROSTATE FOR RETENTION OF URINE.

BY W. PRIOR PURVIS, B.Sc., M.S., M.D. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.

THE patient was 69 years of age. No definite history of urinary trouble could be got from him except that on July 22nd, 1902, he took a long drive and may have partaken of some stimulant at the end of it. That evening he found difficulty in passing his urine and there seems to be little doubt that he had "retention incontinence" up to August 5th, on which date complete stoppage of the flow took place. He was seen by Mr. R. A. E. Bacon and by my colleague, Dr. H. P. Ward, who succeeded in passing a long bi-coudé catheter and emptied the bladder. After this Mr. Bacon, and later his locum-tenent, emptied it twice a day until the 17th. The catheter then refused to pass and Dr. Ward was called in again and was successful in passing it. At this period the patient was in a very grave condition. Rigors were of daily occurrence and hæmorrhage was free at every attempt at catheterisation. On August 19th the difficulty with the catheter recurred and the patient was removed to a nursing home for operation, where I first saw him in consultation with Dr. Ward at 11 A.M. The patient was a very stout man and his abdomen was greatly distended. He was quite unable to micturate and was suffering great pain. His temperature was 99·8° F., his pulse was 100 and regular but only fairly strong, and his respirations were 22 per minute. The condition of his kidneys could not be ascertained, but his other abdominal organs and his thoracic viscera evinced on examination no signs of disease. I was quite unable to pass any kind of flexible catheter, but with one finger in the rectum I managed to introduce a large silver prostatic catheter and drew off a great quantity of dark brown sickly smelling urine. I could feel that his prostate was very large and hard. Owing to the difficulty of passing any catheter and to the fact that it was evident that severe cystitis would soon come on I decided, after consultation, to drain the bladder by an external opening and then to see whether it was possible to remove the obstructing prostate and, if so, to attempt the operation. I chose the suprapubic route because I felt more at home with it and also because I was unable to exclude the existence of cancer of the prostate.

In the afternoon, then, of the same day, under chloroform and with the assistance of Dr. Ward, the distended bladder being distinctly felt, I made a long incision in the middle line immediately above the symphysis pubis. There was a very thick layer of fat in the abdominal wall, but the bladder was easily entered with but little hæmorrhage. There was an immediate gush of urine and on introducing the right forefinger the upper surface of the prostate could be felt forming a circular elevation like a rampart all round the internal urinary meatus. There was no calculus and there were no sacculi connected with the bladder. I introduced the first two fingers of my left hand into the rectum and so pushed forward and steadied the prostate, while with my right forefinger I first scratched through the mucous membrane on the prostate to the right of the urethral orifice and then worked my way between the tumour and what I may call its surgical capsule. The whole of the upper part separated fairly easily, but there was considerable difficulty below and in front where the prostate abuts on the triangular ligament. This, perhaps, was due in a measure to the density of the tissue connecting the tumour with its capsule at that point, but was more owing, as it seemed to me, to the great size of the structure which I was removing, which prevented me from getting my finger far enough round it. The difficulty was finally overcome by tearing the tumour up into four approximately equal portions, the first two fingers being used to do this and to extract the fragments from the bladder. In this case the mucous membrane of the prostatic urethra certainly came away. The tissue left between the cavity and the rectum was very thin. There was a good deal of hæmorrhage for a short time after removal of the fingers from the bladder. This was washed out with sterilised water, the ends of the wound were closed with sutures and a large drainage-tube was inserted right down to the bottom of the cavity formerly occupied by the tumour. I was unable to replace the four portions of the growth in their correct relations or to trace the former position of the urethra. The weight was *six* and a *half* ounces and the *size* was that of a large orange.

---

[21] Brit. Med. Jour., vol. ii., 1900.

The operation was over at 4.40 P.M., but the subsequent course of the case was not all plain sailing by any means. Within an hour a severe rigor set in. The temperature at 6 P.M. was 101·4° and at 9 P.M. 103°, the pulse being 133 and the respirations 40. At 10 P.M. it had begun to abate: the temperature had dropped to 101·2°. That night the patient slept for two and a quarter hours and took milk and brandy. On the next day his temperature at 6 A.M. was 99° and at 6 P.M. it was 100·4°. Never after this did it exceed 100°, but the pulse continued to range from 92 to 104 and the respirations from 20 to 28 for many days. On the third and fourth days his condition caused me some anxiety on account of heart weakness, and he was injected with one-sixtieth of a grain of strychnine sulphate every quarter of an hour, but on the fifth day he could eat a baked custard. On the seventh day a number of large blotches of a purpuric eruption came out on the backs of both hands and lasted about a week, gradually fading away. I am at a loss to account for this. On the ninth day the patient stated that he passed a few drops of urine through the penis, but as his bed was always wet it was impossible either to confirm or to deny his statement. Up to this time the wound had been dressed with pads of absorbent gauze and wool, but as the fat had become very sloughy the dressing was changed on the tenth day to boric acid fomentations. On the eleventh day the patient sat up in a chair for a short time. The wound having become encrusted with phosphates I tried the effect of soaking the lint in a solution (1 in 20) of acetic acid for a few days but without good results. On the thirteenth day he was sufficiently well to dine off chicken, custard, and fruit. On the twenty-sixth day he passed altogether 15 ounces of urine naturally and on the twenty-eighth day Mr. Bacon passed a soft rubber catheter to assist him. The leakage [illegible] and the urine passed more [illegible] on the fifty-seventh day, a [illegible] A few days before this the bladder had been washed out daily through a catheter and this attention was required now and again afterwards until he was finally sent home on the seventy-fourth day. He is now able to walk about and to retain or to pass his urine as he wishes. He says he feels better than he has for years.

Southampton.

A CASE OF ACUTE EPENDYMITIS IN AN INFANT.

BY J. A. COUTTS, M.B. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN.

CASES of primary acute ependymitis leading to the formation of pus in the cerebral ventricles are of such exceptional rarity as to merit that each one should be put on record. Apart from the result of the bursting of a cerebral abscess into their cavities, or as a consequence of suppuration in the sac of a spina bifida, the presence of unmistakeable pus in the cerebral ventricles is a rare occurrence under any conditions. Very occasionally pus in the ventricles is found post mortem in cases of purulent meningitis. Far most frequently, however, the turbid fluid found in even the acutest of these last cases affords no naked-eye appearance of pus, whatever evidence of its purulent character may be forthcoming from microscopical or chemical examinations. The interest in the present case lies in the fact that large masses of pus were found in the ventricles post mortem, without any other lesions being discovered in the meninges or cerebral substance.

Ependymitis as a distinct pathological condition is more frequently dealt with by American writers than by those in this country. References to it, both as an acute and chronic condition, may be found in the works of Delafield and Prudden, Osler, Emmett Holt, and others in America and by Sir William Gowers amongst English authorities. As far as I can gather all these writers treat acute ependymitis from a purely pathological standpoint and merely as a condition discoverable post mortem in connexion with disease of other parts of the brain or its membranes. I know of no instance where an attempt has been made by any writer to connect any symptoms observable during life with the ventricular conditions discovered post mortem. As regards the symptoms arising from the chronic form of ependymitis we perhaps stand on a less uncertain basis. More than 20 years ago, in a graduation thesis at Cambridge, I combated the view that chronic hydrocephalus had any causal origin in rickets and ventured the opinion that possibly an explanation of the former complaint would be found in a primary chronic inflammatory condition of the ventricular ependyma. This view is not inconsistent with the conditions discoverable post mortem and, even if far from satisfactorily established, is, I believe, one very commonly held at the present day.

The difficulty in dealing with the acuter forms of ependymitis lies in the fact that almost invariably the ventricular affection is complicated with other gross lesions of the brain or its membranes and it becomes a matter of impossibility to assign to each separate part its due share in the production of symptoms. In my present case, in the later stages at least, the acute ventricular inflammation was probably the sole disorder and it is no unfair assumption that some of the later symptoms observable during life were directly ascribable to it. As these symptoms, however, were in no sense distinctive or characteristic and varied but little from day to day, I have thought it well briefly to summarise them from the excellent and copious notes of my former house physician, Dr. G. A. Finlayson, now bacteriologist at Singapore.

The patient, a female infant, aged three months, was admitted into the East London Hospital for Children under my care on Nov. 19th, 1902. In the family history of the case there was nothing special to note. The father and mother and two remaining children were healthy. Two children were dead; one had died from pneumonia with measles and the other was found dead in bed. There had been no miscarriages. The patient was a breast-fed infant and had been fairly healthy until the onset of the present illness. This occurred two days before her admission to hospital with diarrhœa and vomiting. The stools, three or four daily, were green and not offensive. The vomiting occurred soon after taking the breast. Early in the morning of the day of admission the infant had a convulsive attack, the arms and legs were held rigid for some time, then twitching occurred in the extremities. The attack lasted about 15 minutes and soon after the child was brought to the hospital. Just before the onset of the fit she seemed to have pain in the abdomen with drawing up of her legs and screaming.

On admission the patient was found to be a small, pale, and rather badly nourished infant. The eyes were bright and the pupils were equal and convergent strabismus was strongly marked. The breathing was irregular both in rhythm and in depth. The pulse varied extremely in force and in rhythm, becoming faster when the breathing was quicker and very slow and almost intermittent when a period of apnœa supervened. There was no definite convulsive attack, but the infant was restless and had irregular spasmodic tremors of the hands. The legs were drawn up on the abdomen and were slightly flexed. Kernig's sign was not present. The knee-jerks were very active—they were brisk and were excited by a very slight tap on the tendon. There was slight retraction of the head but no marked rigidity of the post-cervical muscles. The anterior fontanelle was tense and bulging. The sagittal and frontal sutures were widely open. There was nothing calling for special note in the examination of the chest. The skin was elastic. The tongue was furred. The abdomen was soft and distended. The infant could not take the breast and had to be fed nasally. The temperature on admission was 103° F. but it fell to 101° in the course of a few hours.

The symptoms varied but little till the death of the infant [illegible] as follows. The vomiting [illegible] times a day—generally [illegible] also slight obstinate diarrhœa which continued in spite of treatment until a week before death. After a fortnight in hospital the fits recurred and after this there were few days in which there were not several convulsive attacks. At first these consisted of clonic spasmodic contractions of the left arm and leg and both the mouth and eyes were drawn to the left side. The later attacks were general in character and showed no unilateral tendency. Each fit lasted a considerable time and was ushered in by a shrill scream on the part of the infant. Towards the end they became very frequent. The temperature, which had been 103° on admission, presented from the beginning a marked up-and-down type. At first the maxima attained seldom went much above 101° and on several occasions the temperature dropped temporarily below the normal. Later, when the fits became more numerous, the temperature assumed a higher range and on one or two occasions it went up beyond 104°. The knee-jerks continued exceedingly brisk and a slight tap on the patella tendon would throw the limb into a state of clonic spasm with as many as from 10 to 20 contractions. The head retraction became more marked and the post-cervical muscles more rigid, and towards the end there was considerable opisthotonos. The anterior fontanelle continued very tense and bulging. The day before death an attempt was made to relieve the cerebral tension by drawing off fluid from the ventricles by way of the anterior fontanelle, but this failed owing doubtlessly to the eye of the needle getting blocked by one of the masses of lymph or pus. For the first three weeks the infant remained fairly plump, but before death emaciation became extreme. The total duration of the illness was exactly six weeks.

The following are the notes of the post-mortem examination 18 hours after death, made by Dr. Leonard S. Dudgeon, the pathologist to the hospital :—

> The child was very emaciated. No skin lesions were to be seen or felt. No spina bifida was detected. The pharynx, trachea, lungs, pleura, mediastinal glands, heart, pericardium, and the thymus gland were all found to be healthy to the naked eye. The pulmonary artery was opened *in situ*, but there was no evidence of any ante-mortem clot. The abdominal cavity and its contents, the liver, spleen, kidney, suprarenals, pancreas, stomach, intestines, and glands were all found to be normal. Head.—All the cranial sinuses were normal. There were no abnormal changes in any of the bones of the skull. No middle ear or mastoid disease was noted. Cerebral membranes.—Nothing abnormal was seen to suggest any past or present meningitis. There was extreme flattening of the convolutions. No hæmorrhage or any new growths were seen in any part of the brain substance. There was extreme bulging at the base of the brain in the region of the optic commissure. As soon as the third ventricle was opened a large quantity of thick turbid fluid poured out and also large flakes of lymph and pus. All the ventricles were extremely dilated and contained similar fluid and pus. At the level of the foramen of Magendie there appeared to be complete blocking. There was no dilatation of the central canal of the spinal cord to the naked eye. There was no inflammation of the spinal membranes in the cervical region—in fact, the cord and membranes appeared to be quite normal in this region. An examination of the spinal cord in the dorsal and lumbar region could not be made, but no fluid could be drawn off from the lumbar region of the cord. The fluid from the ventricle was not offensive. The pus was very thick, whitish-green, and very fibrinous. The dilatation of the lateral ventricles was so extreme that the brain tissue only formed a very thin outer wall to the cavities of the ventricles which were extremely dilated in their whole course. There was an extremely thick inflammatory deposit attached to the ependyma of the ventricles which could be scraped off, leaving a rough surface beneath with great dilatation of the veins coursing along the walls of the ventricles. Also a few scattered pinhead hæmorrhages were seen in the walls of the lateral ventricles. Bacteriological examination of the pus from the ventricular cavities.—Cover-slip preparations of the pus showed large numbers of cocci arranged without exception in the form of long chains. Cultures were made on most of the ordinary media. In every case small colonies grew similar in every respect to those of members of the streptococci family. Cover-slip preparations of the pus were made from the growths on the various media and in every specimen examined cocci in the form of very long chains were the characteristic feature. The coccus stained by Gram's method. There was no capsule to be seen to the cocci from the original specimen of the pus. No inoculation experiments were made with the organism. There was no cause discovered for the ventricular infection.

Needless to say the conditions discovered in the ventricles were totally unsuspected before the necropsy. The close similarity of the symptoms to those of meningitis is sufficiently obvious, and during life the case was naturally taken to be one of the post-basic variety of that complaint. That the diagnosis was wrong, as least as regards the variety of any meningitis that may have been temporarily present, is proved by the bacteriological examination, for the organism found was assuredly not the one so commonly associated with the name of Dr. G. F. Still. Whether the streptococcus discovered was a variety of the pneumococcus Dr. Dudgeon prefers to leave unsettled from the data at his disposal. Under this supposition as to the nature of the micro-organism it is, of course, possible that an early pneumococcal meningitis, leading to blocking of the basal foramina, may have at one time existed and cleared up before death. For such an assumption, however, there was absolutely no evidence forthcoming at the post-mortem examination. A more natural and more justifiable conclusion in the circumstances is that, rare as the condition may be, the present case was really one of a primary acute inflammation of the ventricular ependyma. Such an inflammation and its results would be thoroughly compatible with the effects discovered post mortem, and possibly with the symptoms observable during life. As has been said, these symptoms were in the main those of a post-basal meningitis. On the severity and time of appearance of one or two of the symptoms some stress may, perhaps, be laid as lending aid in distinguishing between the two conditions. In the present case the onset was more acute and the fits were much more frequent and persistent than in an ordinary case of post-basic meningitis. The temperature, too, towards the end of the third week began to rise, whilst in most cases of post-basic meningitis it would by that time have reached the normal or fallen below it. One other point seems worthy of some special notice. In a sick infant aged three months only the degree of consciousness present is hard to estimate. The fact, however, that from the moment of her admission to the hospital the infant had lost the power of sucking and had to be fed nasally is strong presumptive evidence that the amount of consciousness appropriate to the age of the child was already in entire abeyance. So early a loss of consciousness, in less than two days from the onset of the illness, is a rare occurrence in any form of meningitis. On the failure to elicit Kernig's sign I would personally place but little weight. The inability to draw off fluid from the ventricle, where one was fairly certain the point of the needle was within that cavity, ought, perhaps, to have led to the conclusion that the case was not an ordinary one of post-basic meningitis, but deductions drawn from such a procedure hardly enter into the domains of practical diagnosis.

The main features of acute ependymitis in infants, as far as one is justified in attempting to settle them from a single case, would seem to be acute onset with vomiting, a persistent temperature of the hectic type rising towards the end of the illness, very early loss of consciousness, very frequent fits dating almost from the onset, and early and persistent bulging of the anterior fontanelle, along with convergent strabismus. I much fear, however, that at the present time the differential diagnosis between such cases and those of meningitis is practically impossible, especially when it is remembered how widely cases of the last disorder vary as regards the prominence and times of appearance of their numerous symptoms.

In conclusion, I have to acknowledge my indebtedness to Dr. Dudgeon, not only for the care which he bestowed on the post-mortem and bacteriological examinations, but for several references to the literature of acute ependymitis that I should otherwise have missed.

Upper Berkeley-street, W.

A CASE OF DROPSY, THE RESULT OF INFLAMMATION OF THE KIDNEYS, TREATED BY LAPAROTOMY.

By HENRY PAUL PLANER, M.D.

In the following article I wish to draw the attention of my fellow physicians to a case of dropsy resulting from inflammation of the kidneys, completely relieved by laparotomy and the treatment following the operation—a case of so much interest that it seems to me to be worthy of publication.

On March 12th, 1902, the patient, aged 31½ years, was admitted to my private hospital after having been unsuccessfully tapped at another hospital, from which she was dismissed as incurable on March 7th, 1902, with the prognosis of her speedy decease. Her condition on admission was as follows. She was very anæmic and had almost a bilious complexion; the lungs were healthy, the heart was not enlarged, and the heart-beats were clear. The liver reached far beyond the right arch of the ribs and was very much enlarged. The spleen was three fingers' breadth beyond the usual limit and painful to touch. The kidneys, according to external percussion and palpation, were enlarged and sensitive to touch. The uterus was somewhat small and moderately retroverted. Menstruation was said not to have appeared for five months. The urine was very albuminous; it was free from sugar. The body was enormously swollen and in a state of advanced ascites. As I was convinced that the patient was suffering from dropsy arising from inflammation of the kidneys, accompanied with rather severe albuminuria, I decided to let off the fluid by means of laparotomy. Under the influence of chloroform at first and later of ether I made a long incision in the abdomen, introducing at the same time into the two breasts, by means of two capillary tubes, a solution of tepid salt water with a small quantity of sodium bicarbonate. During the whole operation the anæsthesia was not interrupted in any way, nor was the action of the heart enfeebled, which was mainly owing to the introduction of the salt water into the system. After opening the abdomen and letting an immense quantity of water rush out I found the liver, spleen, and kidneys very swollen and in a state of extreme hyperæmic inflammation; the suprarenal capsules, uterus, and ovaries were in a natural state; the parametrium and perimetrium, as well as the general peritoneum, were free from any inflammatory matter. After having removed from each side of the incision wound (which was 18 centimetres long) a strip (15 centimetres broad and 40 centimetres long) of the very much expanded peritoneum I united the remaining edges of the peritoneum with a row of catgut stitches to which I joined the muscles and fasciæ and then closed the abdomen with 12 silk stitches. On the fourth day after the operation and every following day until the *forty-second* the patient received on an empty stomach a pill containing gamboge, while the diet was light and free from fat and albumin. This removed the congestion of the liver, spleen, and kidneys, and it became evident that the patient's bilious complexion was giving place to a fresher colour. The motions of the bowels were also regular and spontaneous after medication ceased, whereas they had before been very constipated. The secretion of urine, which had been very scanty and albuminous before the operation, was now plentiful and showed no trace of albumin. On the fifteenth day after the operation the external silk threads could be removed and a week later, on April 2nd, the patient was able to leave the hospital completely cured and without a trace of ascites in her body. For over nine months she has enjoyed perfect health and needs no further medical treatment. At the last examination of the patient, which took place two months ago, I found the abdomen soft, the liver non-resistant, the spleen in a normal condition, the wound well healed (*without hernia of the bowels*), the *urine free from* albumin, the motions daily and spontaneous, and the general health good. The patient informed me that she had accomplished a walk of about ten English miles in three hours when carrying a heavy weight without any inconvenience whatever. I must not omit to mention that six weeks after the operation menstruation caused severe pain, in consequence of which I undertook a slight dilatation of the cervix uteri and after this it came on regularly and painlessly.

From the success of the preceding case I arrived at the conclusion that by the operation of laparotomy the dis- [illegible] greatly relieved, that the [illegible] permanent relief from [illegible] patient was due entirely to the operation of laparotomy, whereas the tapping of the abdomen practised previously by other hands was altogether without effect. It would be interesting to learn whether the same experience has been met with in similar cases in other hospitals. This example tends to show at all events that laparotomy is to be preferred to tapping or puncture in cases of severe ascites.

Dresden.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—Mr. G. Gardner Oakley, M.R.C.S. Eng., L.R.C.P. Lond., of Halifax, has recently been the recipient of a case of pipes from the members of a men's ambulance class whom he has instructed in first aid.—Mr. John Twiname Gardner, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., the chairman of the Ilfracombe band committee, was presented on April 1st, at the last fortnightly concert which he had arranged during the winter months, with a silver cigarette, match, and sovereign combination case and an illuminated address containing the names of 130 subscribers and recording the appreciation of his efforts in providing during the past winter high-class concerts which had been greatly enjoyed by the residents and the visitors.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF NASAL CALCULUS WEIGHING 48 GRAINS.

BY A. J. HELM MONTAGUE, M.D. DURH., L.R.C.P. LOND., M.R.C.S. ENG.,
SURGEON TO THE WORKSOP VICTORIA HOSPITAL;
AND
RICHARD LAKE, F.R.C.S. ENG.,
SURGEON, ROYAL EAR HOSPITAL.

A MARRIED woman, aged 36 years, was seen by Mr. R. Lake, in conjunction with Dr. A. J. H. Montague, on August 4th, 1902. She complained of an offensive discharge from the left nostril, a disagreeable taste in the mouth, and inability to breathe through the nose. The above symptoms had existed for five years. On examination a large calculus was found firmly imbedded in the left nasal cavity. Mr. Lake removed it with forceps, under cocaine, with much difficulty. The calculus weighed 48 grains. The outer crust consisted of earthy carbonates and phosphates and the nucleus consisted of a cherry-stone which when crushed revealed the kernel intact. The patient was given an antiseptic nasal douche and on August 23rd all symptoms had disappeared and she was able to breathe normally through the nose.

Remarks by DR. MONTAGUE.—The points of interest in the case appear to be, firstly, the size of the calculus; and secondly, the fact that the patient had no symptoms until five years ago and that she had no idea how the cherry-stone got up her nose. On careful inquiry it was elicited from the patient that she *distinctly remembered*, when a small child, living in a house in the country to which was attached an orchard containing several cherry trees. Doubtless one of her playmates, or she herself, pushed the stone up her nostril, the stone remaining quiescent for many years.

NOTE ON A CASE OF MACROPODIA.

BY DR. R. KUTSCHERSKY.

(*Translated for* THE LANCET.)

THE patient in this case is a beggar-woman who is 60 years of age and has an abnormal development of the right foot. Not much information as to her past history can be obtained from her; she says that she was born with her foot in this condition, that it grew with her growth, and that there never have been any instances of malformation in her family. Her body is in other respects well developed; her muscles are of average strength; the subcutaneous fat is scanty. Her height is 163½ centimetres (5 feet 5 inches); on several parts of her body there are small cutaneous ulcers of unknown origin and not attended with pain; in other respects her body presents nothing abnormal. The right foot is considerably larger than the left one and makes with the leg a much greater angle than the left foot does; its anterior half is strongly curved, so that the toes do not touch the ground but point upwards. The conformation of the toes at once attracts attention, especially that of the great toe and the second and third toes; they are enormously large and thick, strongly curved upwards, and extremely divergent from one another. These three toes are ankylosed in all [illegible] they are not capable of either active or [illegible]; whatever is to be [illegible] the second toe are simply extended upwards in a marked degree, whilst the third toe is dislocated upwards and backwards; the two other toes (the fourth and fifth) are hardly noticeable where they project from under the third one and by contrast they seem to be smaller than normal. The toe-nails are proportionately enlarged without any anomalous feature. The following measurements were taken: the length from the heel to the extremity of the second toe is 30 centimetres (11·8 inches) in the right foot and 24 centimetres in the left one.

The circumference of the right foot at the root of the toes is 34 centimetres, while that of the left one is 25 centimetres. The circumference of the right great toe at its root is 13½ centimetres, that of the left one being eight and a half centimetres. The distance between the great toe and the second toe of the right foot is 16 centimetres at their extremities and three centimetres at their roots. The woman has no paresis or disorder of sensibility or other anomalous condition of the nervous system; neither has she any functional disorder of the internal organs.

GUNSHOT INJURY TO THE LEG FOLLOWED BY ALBUMOSURIA.

BY C. E. CAMPBELL-HORSFALL, M.B., CH.B. VICT.,

LATE HOUSE PHYSICIAN TO THE LEEDS GENERAL INFIRMARY AND HOUSE SURGEON TO THE CHILDREN'S HOSPITAL, LEEDS.

THE patient, a working man, was accidentally shot in the leg below the knee, the injury being so severe as to necessitate immediate amputation. He had lost a considerable quantity of blood previously to his admission to the Clevedon Cottage Hospital and was profoundly collapsed after the operation. He rallied, however, and made an uneventful recovery. The urine was not examined on admission. Two days later it was found to contain a large quantity of albumose On boiling the urine, previously acidified, a copious precipitate was thrown down which entirely disappeared on further heating, reappearing on cooling again. On applying Heller's test a dense white cloud formed some distance above the line of contact of the two fluids. This cloud entirely dissolved on heating but it reappeared on cooling. This condition lasted several days, the albumose growing less each day until it entirely disappeared, and it has not since returned.

The clinical significance of albumose in the urine is at present imperfectly understood. It occurs in many conditions and is found most frequently where destructive tissue changes are taking place under the influence of micro-organisms—e.g., infective diseases, pus formation, &c. It is also found in cases of Bright's disease, pregnancy, and insanity. It occurs abundantly in the condition known as myelopathic albumosuria, sometimes appearing in the urine as a thick white deposit. In this condition it is dependent on sarcomatous degeneration of the bone marrow and is, of course, of fatal significance.

GREAT NORTHERN CENTRAL HOSPITAL.

A CASE OF SUPPURATING HYDATID CYST OF THE LIVER WITH GALL-STONES IN THE GALL-BLADDER, THE SYMPTOMS SIMULATING THOSE OF BILIARY COLIC.

(Under the care of Dr. H. W. SYERS.)

THE patient, a married woman 37 years of age, was admitted into the Great Northern Central Hospital on August 20th, 1902, under the care of Dr. H. W. Syers. With the exception of the occasional passage of tapeworm during the last 12 years (no such passage having occurred during the last two and a half years) the patient stated that she had always been in good health until early in the year. Then, without apparent cause, she first complained of pain after food and epigastric tenderness. For these symptoms she sought relief at a hospital, being admitted and remaining as an in-patient for 14 days, the illness being regarded, according to the patient's statement, as gastric ulcer. There was no jaundice at this period. She afterwards attended as an out-patient at the same hospital during the next four months. The diagnosis which was made appears to have been "gastritis" and she was treated with aperients and bitters with alkalies. A month before admission to the Great Northern Central Hospital she began to suffer with severe attacks of abdominal pain accompanied with occasional vomiting. A fortnight before admission jaundice was first noticed and affected the whole body. There was severe pain in the right hypochondriac region and there was an account of a swelling in this region which came and went, being also very painful. It seems that the pain was always severe during the time that the swelling was in process of evolution and during its continuance, but that the latter was of short duration and that with the disappearance of the swelling the pain vanished. The family history was not material. The patient had borne two children, one of whom had died five years before from "fits" at two years of age, while the other was living and healthy.

On admission the patient was found to be thin and delicate in appearance. She lay in bed on her back and was breathing rather rapidly. There was distinct jaundice affecting both skin and conjunctiva. The lungs and heart were healthy. The abdomen was somewhat tense and there was marked tenderness on pressure below the right costal margin. The tenderness was particularly evident over the junction of the tenth costal cartilage. In the right hypochondrium just below the costal arch a mass could be felt which appeared to be the distended gall-bladder, but no definite increase of size on the part of the liver itself could be made out. The urine was bile-stained but there was no albumin. On the next day the tenderness in the hepatic region was less marked; the jaundice, too, was not so evident and there was some bile in the evacuations. The temperature, which had been 101·8° F. on and after admission, remained more or less elevated until the 26th, when it fell to the normal. The jaundice had now greatly lessened and there was practically no pain in the hepatic region. On the next day, however, the condition of the patient was as bad as ever. The temperature rose and on the 27th it was 102·4°. On this day a very definite swelling appeared in the region of the gall-bladder; this swelling was extremely tender and painful, but the next morning it disappeared, leaving the patient much more comfortable. With the disappearance of the swelling the temperature again fell to the normal and remained normal until the 29th. During these two days the condition again greatly improved, the jaundice becoming much less marked and the pain in the right hypochondrium disappearing. On the morning of the 29th a relapse occurred. The patient had slept well the previous night and was fairly comfortable all the morning. At 1 P.M. she was suddenly seized with severe pain in the hepatic region which continued all the afternoon. There was some nausea but no actual sickness. At 3.30 P.M. she stated that she felt the ' lump coming." At 6 P.M. a definite rounded elastic swelling of the size of an orange was felt beneath the abdominal wall about three fingers' breadth below the costal margin; it was acutely tender on pressure. On the next morning the lump had entirely disappeared, the temperature had fallen to the normal, and the patient was very comfortable. On this day Mr. E. C. Stabb saw the case with Dr. Syers and it was decided to operate.

The operation was performed on the next day (Sept. 1st). A vertical incision was made just below the ninth rib in the right semilunar line and the abdominal cavity was opened. The gall-bladder, of natural size, was found just beneath the wound; in it were found three gall-stones which were loose and easily moveable in the bladder. The three gall-stones were so faceted as to form together a sausage-shaped mass about one and a half inches long by half an inch in diameter. These were the only gall-stones that were felt and nothing else which was likely to obstruct the passage of bile could be detected. The head of the pancreas could be felt and was apparently normal. A chain of enlarged glands extended along the course of the common bile-duct. The liver was apparently normal in size; the lower margin was sharply defined and on a level with the costal margin. No soft spot or bulging could anywhere be detected. In the region of the gall-bladder the anterior surface of the liver was firmly adherent to the overlying costal cartilages by much firm fibrous tissue, evidently of old standing and inflammatory in origin. The under surface of the liver appeared to be absolutely normal.

A small incision was made through the fundus of the gall-bladder and the stones were removed. The wound was closed by means of a few stitches in the mucous membrane and a double row of Lembert's sutures externally. The abdominal incision was then closed with fishing-gut and superficial horse-hair sutures. On the next day the temperature was normal and the patient on the whole was fairly comfortable. There was slight pain in the right hypochondrium and she vomited, but not severely, once or twice. The bowels were opened by means of enemata and the vomiting did not recur. The condition continued fairly satisfactory; the sutures were removed at the end of a week, the wound having completely healed by first intention. On the 8th the temperature had again risen slightly; there was now marked tenderness over the epigastrium and the vomiting recommenced, the temperature rising to 102°. She remained in much the same condition until the 18th, when a distinct change for the worse took place. Marked and general jaundice now appeared and vomiting again became troublesome. The temperature was still 102° and severe pain in the left lateral region of the chest was complained of. On physical examination there was found to be acute dry pleurisy in this locality. There were also much pain and tenderness in the right hypochondrium and in the epigastrium. No improvement occurred during the next few days. Pleural friction sounds were clearly audible over the left lateral region and great pain was complained of in this locality. On the 16th it became obvious that the patient was suffering from acute peritonitis; the jaundice persisted, the temperature remained high, and the vomiting was uncontrollable. She died on the 18th, all the symptoms of acute general peritonitis being well marked and deep jaundice being present at the time of death.

Necropsy.—The post-mortem examination was made the day after death. The body was universally and somewhat deeply jaundiced and was also greatly emaciated. On opening the abdominal cavity acute purulent peritonitis was found to be present; the intestines were greatly distended with gas and were covered with recent lymph at numerous points at which they came into contact with one another. The peritonitis was most intense in the upper half of the abdominal cavity and especially in the right hypochondrium. It was found that an abscess had burst through the lower surface of the liver in the neighbourhood of the transverse fissure and that the extravasation of its contents had set up an acute purulent peritonitis. On removal of the liver the whole central portion of the organ proved to be the seat of an enormous hydatid cyst, the contents of which had suppurated. The cyst lay beneath the dome-shaped surface of the liver and was separated from the diaphragm, to which the liver was strongly adherent, by not more than an inch thickness of healthy hepatic tissue. The cyst was fully six inches in diameter and was situated quite two inches from the front of the liver. It contained large numbers of daughter cysts. In the course of the extension of the hydatid cyst an opening had resulted into the common bile duct, through which the contents of the cyst could escape into the duodenum.

Remarks by DR. SYERS.—The diagnosis in this case was by no means easy or straightforward. The severe paroxysmal pain from which the patient suffered taken in connexion with the attacks of jaundice which certainly seemed to be more or less consecutive to the paroxysms of pain, together with the periodical swelling which occurred in the neighbourhood of the gall-bladder, led to the suspicion that the case was one of gall-stone colic, and as at the operation gall-stones were actually found it seemed that the case was clearly explained and no further interference was deemed necessary. Indeed, the condition of the patient previously to the operation was very far from satisfactory and it would not have been advisable in any circumstances to have prolonged the operation. It may be safely assumed that the periodical swelling which occurred below the right costal margin was due to distension of the gall-bladder. As regards the persistent jaundice, it may remain an open question as to whether this was the result of impaction of gall-stones or whether it may not have been due to a blocking of the bile-ducts by the inspissated contents of the hydatid cyst. For some days after the operation the state of the patient was so satisfactory as to render it probable that the removal of the gall-stones had effected a cure, but the appearance of severe symptoms at a later stage rendered it obvious that some deeper-seated lesion was present. The rapid increase in the severity of these symptoms precluded the possibility of further operative interference and it is certainly a question whether in any circumstances an abscess situated in the very centre of the liver could have been successfully treated by incision and drainage from behind. The risk of injury to the base of the right lung would have been very great and the discharge of the contents of the suppurating hydatid cyst into the right pleural cavity would also very probably have occurred. The cases in which the abscess points externally and presents from the upper or under surface of the liver are totally different and are far more easily diagnosed and surgically treated.

PATHOLOGICAL SOCIETY OF LONDON.

The Action on Bacteria of Electrical Currents (or Discharges) of High Potential and Rapid Frequency.—A Further Note on a Case of Multiple Granulomata caused by a Higher Mould Fungus.—A Case of Streptothrix Infection.—The Influence of Salts on the Action of Immune Hæmolysins.—Note on the Serum Reaction of Tubercle

A MEETING of this society was held on April 21st, Dr. E. E. KLEIN, F.R.S., the Vice-President, being in the chair.

Mr. ALEXANDER G. R. FOULERTON and Dr. A. M. KELLAS communicated a paper on the Action on Bacteria of Electrical Discharges of High Potential and Rapid Frequency, in continuance of a communication on the same subject which they made at a laboratory meeting of the society last year. In the former communication they had given the results of their earlier experiments, which showed that by discharging the current close to the surface of a fluid containing bacteria, held in a test-tube through the bottom of which a platinum wire had been sealed, it was possible to destroy the organisms suspended in the emulsion. The organisms tested in this way were bacillus typhosus, bacillus coli communis, bacillus dysenteriæ (Flexner), bacillus anthracis (sporing and non-sporing cultures), bacillus pyocyaneus, bacillus prodigiosus, staphylococcus pyogenes aureus, and streptococcus pyogenes. The emulsions were made either by mixing bacterial growth from a solid medium
with distill
culture to
of from 2 5 to 5 ampères, the voltage varied from 35 down to 24, and the experiments were carried out in an atmosphere of common air. Sterilisation of the bacterial emulsion occurred after exposure to the discharges of from 10 to 20 minutes' duration, varying apparently with the intensity of the current employed. Further experiments had now been carried out to determine the precise cause of the sterilisation, and it was found that if the experiments were carried out in an atmosphere of hydrogen instead of in one of common air the bacteria would survive an exposure to the discharges of at least one and a half hours, beyond which time their experiments had not at present extended. It had also been found that the bacteria remained unaffected when the discharge was sprayed in an atmosphere of hydrogen over the surface of a growth in a sloped agar tube, through the bottom of which a platinum wire was sealed as before. Further, it was found that when such currents were discharged over the surface of water in an atmosphere of common air under the condition of the previous experiments there was a rapid development of acidity in the fluid, due to the formation of nitrous and nitric acids from nitrogen peroxide formed by the discharge of the current in the air. The nitrous acid was, under the conditions of the experiments, rapidly changed to nitric acid; and it was to the latter that the germicidal action must be mainly attributed. Nitrogen peroxide being formed in the air as the result of the electrical discharge, the latter when it took place at the surface of the fluid seemed to favour the solution of the gas, to carry it down into the fluid as it were; and it was possible that with the discharge of such currents over the skin a somewhat similar penetration of the chemical products might occur. In any case it seemed probable that the discharged current had very little direct action on bacteria with exposures of moderate duration, and the useful effect of the discharge of current in certain conditions when ulceration was present must be taken as being due, at any rate

to the germicidal action of chemical decomposition products formed in the air. And it was possible that in morbid conditions, not apparently caused by parasitic infection, the favourable results sometimes observed might be in part due to the action of nascent and active nitrogen compounds penetrating the tissues in minute quantities. And, as already stated, it was not unlikely that the electrical discharge on the surface might favour the penetration of the skin by such bodies. Experiments in which the currents were sprayed over the bacteria in an atmosphere of carbonic acid had also been carried out, but the results were somewhat contradictory and further experiments were necessary.—Dr. KLEIN pointed out that although Mr. Foulerton and Dr. Kellas came to the conclusion that the bactericidal power of the electrical discharges was due to chemical change and not to the direct effect of the current, yet they had not explained why certain organisms which had a considerable resisting power to chemical disinfectants were killed as readily as those with a lesser resisting power.—Mr. FOULERTON, in reply, said that tubes containing various organisms had been exposed to the electrical discharges for periods of five, ten, 15, or 20 minutes. One growth might be killed by exposure for just over 15 minutes, while another growth might not be killed till nearly 20 minutes' exposure; in the present series of investigations no account had been taken of these differences and therefore he thought that the inconsistencies referred to by Dr. Klein were more apparent than real.

Dr. W. S. LAZARUS-BARLOW referred to a case of Multiple Granulomata which he had described at the meeting of the society on Jan. 20th of the present year and said that further events had shown that the fungus which he had suggested might be the cause of the disease was not so in reality. He had suggested that the cause of the multiple granulomatous tumours was a hyphomycetous mould which he had obtained in pure culture. Since then the man had returned to hospital with fresh abscesses from which had been isolated a streptothrix identical with one isolated by Mr. Foulerton in a somewhat similar case. It was this latter which must undoubtedly be looked upon as the cause of the condition particularly as it corresponded with masses of the organism that were actually present in the tissues.

Dr. W. D'ESTE EMERY showed Specimens and Cultures from a case of Streptothrix Infection under the care of Mr. A. B. Barrow in King's College Hospital. The patient was a woman who resided in the country. The infection apparently occurred through a carious tooth which was removed. This led to no relief and after a time numerous sinuses formed in the skin in the region of the lower jaw, face, temporal region, and upper portion of the chest; the tissues in this region were hard and infiltrated and the skin was reddened. The pus contained typical nodules of streptothrix. Little improvement took place when the patient was treated with large doses of iodide of potassium, but when this was supplemented by incisions and scraping of the sinuses rapid amelioration occurred. Cultures were obtained and the organism was found to grow on all ordinary media at blood heat in the form of small, discrete, opaque, white colonies. They grew best on potato. The growth on blood serum resembled small pearls and the medium was not liquefied. The organism grew both in the presence and absence of oxygen and apparently slightly better in its absence. In anaerobic cultures typical "chain sporulation" occurred and the mycelium often showed terminal clubs, sometimes of very large size. In aerobic cultures the organism occurred almost entirely in the form of straight bacilli, mycelia being very scanty or entirely absent. Dr. Emery considered that these bacilli multiplied by simple transverse fission without the intervention of a mycelial stage.—Mr. FOULERTON said that when dealing with a quickly growing organism it was easy to trace the various steps of development, whereas when the organism was slow-growing the various stages merged into one another.

Dr. W. BULLOCH described experiments on the Influence of Salts on the Action of Immune Hæmolysins. He showed by a new method of preparing the stromata of the red blood corpuscles that the formation of hæmolysins was referable to the nucleo-proteid, as stromata which have been extracted with ether were incapable of developing hæmolytic sera. Certain salts, such as sulphate, bromide and chloride of magnesium, zinc sulphate, and ammonium sulphate, were capable of completely inhibiting the hæmolytic effect of potent immune sera. By analytical experiments with special reference to magnesium sulphate it was shown that this was due to the salt preventing the junction of the complement with the immune body and not due to the destruction of either of the components of the hæmolysin.

Dr. A. E. WRIGHT described the technique for preparing the fluid to be used in the Serum Reaction of Tubercle. He said that to prepare the fluid tubercle bacilli were ground up in an agate mortar with salt. This was then mixed with water and the mixture centrifuged, when an opalescent fluid remained. When this was brought into contact with a specific serum a sedimentative reaction set in. He next dealt with the forces which caused the sedimentation and suggested that the force was an electric one and acted on the particles, causing them to form into definite groups. The blood serum of tuberculous patients tested in this manner showed no more reaction than the normal blood and Dr. Wright did not consider that the reaction could be of diagnostic value. After tuberculin inoculation a reaction was produced, and by repeated inoculation a cumulative effect was obtained which could be estimated by means of this sedimentation test.

SOCIETY OF ANÆSTHETISTS.

Discussion on Somnoform.—Election of Officers.

A MEETING of this society was held on April 3rd, Mr. WALTER TYRRELL, the President, being in the chair.

Mr. W. FOSTER CROSS read a paper on Somnoform. He said: I have been asked to occupy your time for a few minutes this evening in opening the discussion. I shall not make a great demand on your patience. This anæsthetic on which I wish to speak was first introduced to the public just about a year ago under the name of "somnoform." In May of last year Dr. Rolland and Mr. F. Field Robinson communicated a paper to the British Dental Congress at Shrewsbury upon a new mixture which they had been using as a general anæsthetic. This mixture was composed of the following ingredients: ethyl chloride, 60 parts; methyl chloride, 35 parts; and ethyl bromide, five parts. The following points were claimed in its favour: (1) that all bulky apparatus was dispensed with, all that was necessary being a flask containing the mixture about six inches in depth and holding about 50 cubic centimetres and a face-piece in the form of a cone upon which to administer it; (2) its rapidity in effecting anæsthesia; (3) its rapid elimination; (4) the absence of any untoward effects both during and after administration; and (5) its absolute safety. What struck me most when reading their paper was the statement that anæsthesia could be obtained in 20 seconds and with absolute safety, that no after-effects such as vomiting occurred, and, further, that not only had they used it in minor surgical operations, but in such major operations as removal of the kidney, &c. Now it seemed to me that if these claims were well founded it would be an ideal anæsthetic in busy hospital practice, so I determined to try it and naturally began with some trivial operations, such as extraction of teeth. From these I proceeded to those of greater duration. Now before giving my experience, which I must say is very limited, as I have used somnoform in only about 160 cases, a large proportion of which were those of extraction of teeth, let me first say a word or two upon the method of administration as described by Dr. Rolland. He says that about five cubic centimetres are to be sprayed upon the inner surface of the mask, which is then to be rapidly applied to the face of the patient so as to exclude all air; the patient is then told to breathe. Anæsthesia will then, it is said, be obtained in about 20 seconds, when the eyes become fixed and the arm raised will remain in a cataleptic state or drop owing to muscular relaxation. In administering this anæsthetic I adhered as closely as possible to the rules laid down by Dr. Rolland. I will now pass on to say a few words on the symptoms which I observed. The evident feeling of suffocation and the consequent gasping for breath were much more marked than in any other anæsthetic. This is no doubt due to the almost complete exclusion of air and although this symptom lasts for only a few seconds it is a distressing and disconcerting one and the consequence is that there is a great tendency on the part of the patient to pull away the mask, a tendency which, of course, has to be restrained. So much so did I find this to be the case that I took to administering it through an ordinary celluloid face-piece with the hole at the top lightly plugged with lint. By this means the *struggling was lessened and swallowing movements* which otherwise took place did not occur. As regards the time occupied in rendering patients insensible, I found that it varied as to whether air was excluded or not. In the former case, notwithstanding the attempted resistance *on the part of the patient, anæsthesia was frequently* induced in as little as 20 seconds, the time mentioned by Dr. Rolland. In the latter case about 60 seconds elapsed before anæsthesia was complete, but if free admixture of air was allowed it was difficult to effect true anæsthesia at all and only a condition of analgesia was obtained. Now at first sight I confess that it appeared somewhat difficult to say at what moment the patient was ready for operation, but after administration in a few cases and more or less determining how much air to admit I found that the patient soon settled down and presented the following phenomena. The face in all cases at first became flushed and cyanosis was never observed, except in two *instances which I shall presently mention. The breathing,* which at first was irregular, within a very few seconds became steady, slow, deep, and regular, much the same as occurs in chloroform anæsthesia. The eyes were suffused and had a fixed stare; the pupils which at first were widely dilated within, as a rule, less than a minute became contracted and remained so throughout the administration, with *also loss of conjunctival* and corneal reflexes. The pulse always became rapid at first but soon settled down and became regular, although somewhat increased in frequency throughout the operation. As regards muscular relaxation, in some cases it was perfect, whereas in others this was not so. As an instance of the latter I may mention the case of a boy to whom I administered somnoform for 15 minutes for amputation of the finger and although apparently anæsthetised he was yet constantly moving his fingers on the hand operated on, though there was no movement elsewhere. These movements still occurred even when the administration of somnoform was increased. Afterwards he told me that he felt as if someone was gnawing at his finger, *although the imaginary gnawing gave him no pain. Hence* it seems to me that somnoform cannot be relied upon as a satisfactory anæsthetic where complete muscular relaxation is imperative. I am bound, however, to say that the absence of complete relaxation may possibly have been due to faulty administration, but I must add that this is far from being the only case in which similar symptoms were observed. On the other hand, *I have given somnoform for operations on* particularly sensitive organs with no such symptoms occurring. Now Dr. Rolland claims that anæsthesia may be obtained for as long as five minutes from a single administration. I cannot say that from a single administration I have ever obtained an anæsthesia with a duration of more than 80 seconds, although this is as long again as that obtained from nitrous oxide. But as regards dental practice I do think that it possesses these advantages over nitrous oxide: that not only is the anæsthesia as a rule longer but there is absence of cyanosis and jactitation and that on the whole the patient is quieter. This result of course may be obtained equally as well by the combination of nitrous oxide *and oxygen, and when questioning patients afterwards* who on previous occasions had been subjected to gas, they almost *unanimously told me that they much preferred that* anæsthetic to somnoform. It is further said that dieting is immaterial as no vomiting occurs, also that the position and clothing of the patient are of minor importance, but in answer to these claims I must say that I consider *that dieting ought not to be disregarded any more than* in any other anæsthetic. In three of my cases there has been vomiting; in two of these the stomach was full of solid food and I must say that at first I was somewhat alarmed as during anæsthesia these patients suddenly became pale, with profuse sweating and shallow breathing and with the pulse rapid and very feeble, and then the contents of the stomach were expelled. In another case that I know of, although not within my personal experience, where somnoform was given for dental extraction, the patient vomited occasionally for several hours afterwards; and in another case which I was told of—that of a woman, aged 30 years, to whom it was also given for dental extraction—fainting occurred and the patient remained in a collapsed condition for over an hour. As to its absolute safety happily I can say nothing to the contrary with certainty, but I have notes of two cases in which there were indications of a condition that might possibly have led to fatal results. In both of these cases there occurred *during the administration very marked general rigidity,* with arching of the back, spasm of the muscles of the jaw, and some degree of cyanosis with the pupils widely dilated. It is true that these symptoms were overcome by allowing the patient to have a few breaths of air, and I do not therefore desire to *lay too much stress upon them; but I think it* right to mention this in connexion with the claim that by no possibility can somnoform anæsthesia result fatally. As to the return of consciousness being immediate, I cannot say that this was invariably the case, although it was so in the majority of instances. In one case, that of a child who was operated on for circumcision, six minutes elapsed before conciousness returned, and in another case, that of a boy who was "under" for ten minutes for the extraction of a bullet from the thigh, recovery took as *long as 30 minutes. Moreover, it is to the disadvantage* of somnoform that it has a very disagreeable odour, due, it is said, to the presence of bromide of ethyl. Somnoform is *also, I believe, very liable to decomposition and when kept* for any length of time it loses its efficiency and becomes of a yellowish-brown colour, owing, I understand, to free bromine being given off. I must say a few words about the cost of somnoform. The cheapest price at which it can be obtained is, I believe, 6*s.* per bottle, and this is said to contain enough to anæsthetise from eight to ten *patients, so that this works out at very much more* than the cost of chloroform or ether, with results in my experience not nearly so perfect. On the whole I have come to the conclusion that somnoform possesses few, if any, advantages over the ordinary anæsthetics in daily use, besides *having the particular disadvantages which I have attempted* to indicate. I am not disposed, therefore, to advocate its use. However, as I have already said, my experience of this anæsthetic has been but very limited and I shall be very glad to have the advantage of listening to the remarks of anyone who has had the opportunity of making a greater use of it than I have enjoyed.

The PRESIDENT, after proposing a vote of thanks to Mr. *Foster Cross for his interesting paper, said that personally he* had no experience with somnoform and had never given it. It was certainly not, as far as he could judge, going to take the place of gas. With regard to vomiting, it compared very badly with nitrous oxide, under the administration of which only about 1 in 1000 had vomiting.

Dr. R. H. J. SWAN said that he had used somnoform in *the dental department at Guy's Hospital on about 500* patients. He had used a cornet-shaped mask and had the same results to record as had been described by Mr. Cross—i.e., vomiting and struggling—but had soon come to the conclusion that the mask was an unsatisfactory thing and had used since a celluloid mask with lint inside so as partially to block the holes and to which was attached a Clover's bag; with this he had given somnoform with excellent results. As a sign of anæ[illegible] relaxation of muscular power wa[illegible] was difficult to go on with [illegible]wing whether the patient was [illegible] He found that the best plan was to ask the patient to look at his (Dr. Swan's) finger which he kept moving backwards and forwards in front of the patient's face. In about from 15 to 18 seconds the eyes became fixed, the breathing deeper, and anæsthesia quickly followed. He had produced anæsthesia in some cases in from 90 to 100 seconds, in others in from 35 to 40 seconds. Recovery was not rapid; the patient was very quiet. In few cases was there muscular rigidity. He *had used somnoform for operations* on tonsils, *for adenoids,* [illegible] ence it was unsatisfactory. With regard to cost as compared with that of gas, when giving somnoform with a closed celluloid mask he found the dose recommended, five cubic *centimetres,* [illegible] that a bottle [illegible] was about th[illegible] somnoform [illegible] drug cost rather *more,* but the anæsthesia produced was about twice as long as that of gas, so here there was a saving, as patients did not come round too soon and require a second *administration,* which was often the case with gas. As to the unpleasant smell, this was not very bad, as several patients he had had preferred somnoform to gas. He found that if the patients were prepared beforehand for the disagreeable odour they would take it easily and not complain of a feeling of suffocation which was often experienced under gas. He had not had much struggling except in cases of young children. Dr. Swan then gave some results of experiments upon animals with the drug, it having been given to a cat for over eight hours, at the end of which it was purposely killed. In the case of both dogs and rabbits it was found that the respiratory movements ceased before the cardiac movements. The blood was noted before and after anæsthesia and no change was found in the quantity of hæmoglobin or the white corpuscles. As to the future use of somnoform Dr. Swan thought that it ought to be restricted to short operations and should be given in an inhaler with a bag attached. He had had only one case which gave rise to anxiety, that of a little boy, aged seven years, who was under somnoform for 20 minutes, 18 cubic centimetres being given. When taken back to bed he was in a collapsed state and remained so for six hours. Dr. Rolland had informed him that he had had two bad cases, one being that of a woman, aged 32 years, with whom he had used the cone and induced anæsthesia for 20 minutes. She had had continual fainting and swoons for some time after. The other case was that of a child operated on for adenoids, 10 cubic centimetres being given with similar results. In conclusion he thought that somnoform should have a further trial.

Mr. Edgar Willett said that he would like to make a few observations about some cases (about 20 in all) of his own, some dental, others for minor surgery, such as opening abscesses in young adults; and his experience corresponded very closely with that of Mr. Cross, he having been able to produce anæsthesia very quickly in about from 16 to 20 seconds. The sign he had gone by was loss of the corneal reflex. There was no obvious sensation during operation, but it had been difficult to obtain complete relaxation of the muscles. The patient said that he had no pain. One of his cases was that of a little boy, aged seven years, for a prolonged operation on the thigh which had to be excised and flushed and sewn up. The operation lasted about 12 minutes. The amount of anæsthetic used was 20 cubic centimetres, small doses frequently repeated being given. The boy became very rigid and once opisthotonos had set in. After the operation he had vomited a good deal, which was one of the symptoms usually believed to be absent with somnoform. The points in its favour were, said Mr. Willett, its portability, its extreme easiness in administration, and its quick action. He did not, however, feel disposed to give it a further trial because he considered gas and oxygen very much better.

Dr. Dudley W. Buxton said that as his experience of the administration of somnoform was slight he proposed to deal with another side of the subject. In the original article of Dr. Rolland some remarks appeared on what was called the physiological action of somnoform. But neither in this article nor in any of the subsequent ones was any serious attempt made to investigate the subject. The admitted composition of the mixture seemed to point to the supposition that the predominant partner was undoubtedly chloride of ethyl. The addition of the chloride of methyl, one which he (Dr. Buxton) believed was not original to Dr. Rolland, but was employed in the so-called "coryl" mixture, possessed a doubtful value, while the small quantity of bromide of ethyl which appeared in somnoform could hardly subserve any purpose other than that of giving the mixture a wicked odour. The Society of Anæsthetics ought, he thought, to record emphatically its censure upon the employment of such fancy and misleading proprietary names as "somnoform," "narcotile," "kelène," &c., and should encourage a careful physiological research upon the action of any new anæsthetic agent before recommending its adoption. But Dr. Swan had mentioned an experiment upon a cat. This experiment was really typical of the unsatisfactory tests which had been applied to somnoform. The cat in question undoubtedly died from asphyxia and incidentally inhaled somnoform during the process. As far as one could at present see somnoform was merely a proprietary and costly form of chloride of ethyl and he (Dr. Buxton) thought its superiority to chloride of ethyl had yet to be proved.

Dr. W J. McCardie observed that he had given ethyl chloride 600 times and that when somnoform first came out he had compared the two and had found no difference. Inventors claimed for somnoform that it was so safe that it could be administered to female patients without taking off their corsets, which was a most ridiculous assertion. The great objection to somnoform was the smell produced by the 5 per cent. of ethyl bromide in it. He could not see any use in this small percentage nor in the introduction of the methyl chloride. It was, he urged, better to use the ethyl chloride alone. It was difficult with somnoform to get relaxation of muscles, but if pushed far enough this might be obtained. Dr. McCardie mentioned a case of trismus in a man with abscess. The mouth was tightly closed. Somnoform was given and the muscles relaxed, allowing a wedge to be placed between the teeth. He considered that Dr. Dudley Buxton had struck the right note in objecting to the name. He (Dr. McCardie) had pointed out to the agent the impracticability of using a drug of unknown composition. It was a most objectionable method of bringing a new drug before the public.

Mr. Harvey Hilliard said that he had used somnoform in the throat department and dental department of the London Hospital in about 200 cases altogether and his experience had been coincident with that of all the other speakers because he had used two methods of administration—the mask recommended by Dr. Rolland and also an Ormsby's inhaler. If given in the mask he found that to produce really deep anæsthesia took very much longer than if given in an Ormsby's inhaler, even as long as one minute or longer. He had seen Dr. Rolland administer the anæsthetic to several cases for tooth extraction and did not consider the patient really anæsthetised; there were much struggling and screaming and the patient was not still enough. Finding the result unsatisfactory he had discarded the mask and used Braine's Ormsby's inhaler. Very excellent results were produced in from 20 to 30 seconds and the quantity used was very much less. The signs of anæsthesia, then, invariably were tracheal stertor, dilatation of pupils, loss of light reflex and loss of corneal reflex, and complete muscular flaccidity. Instead of five cubic centimetres, half was ample for young adults and a quarter of five cubic centimetres produced anæsthesia in 15 seconds in young children. The anæsthesia was very quiet and lasted from one to five minutes, according to the time taken for induction. In adults this took longer than in children. The after-effects were a great drawback to the employment of the drug. When used with Rolland's mask vomiting was common. In half the cases he had had vomiting, but none with the closed method. The symptom most complained of was headache, not immediately, but some hours after. A student to whom he had given somnoform for a dental extraction had said that it was "quite as pleasant as gas, bar the smell." This student made a good recovery without nausea or headache and they parted quite good friends, but next morning he (Mr. Hilliard) was told that the student, having suffered terrible headache and nausea for the rest of the day, was waiting for him with a gun. In another case in private Mr. Hilliard unhappily had given it to a girl, aged 14 years, for a dental extraction; the child was to have returned for a second dose but had suffered so much headache that she refused to come again. He thought that somnoform had no advantage over gas and air except for young children for the removal of tonsils and adenoids and he thought that in that particular class of case somnoform was of some value; but in these cases he had had equally good results with bromide of ethyl. For long operations he thought that it would be distinctly dangerous to give it in a closed inhaler because the operator would not be able to avoid an uneven depth of anæsthesia; at one moment the patient would be deeply, and the next lightly, "under" according to whether a fresh dose of the drug had just been put in the inhaler or not and he did not consider that this was a satisfactory way of giving anæsthetics.

Dr. H. P. Noble was anxious to draw attention to two points; one was the diminution in bleeding after tooth extraction and after removal of adenoids and tonsils and the other was that if the patient was warned of the unpleasant smell and was told to breathe quietly there were no sense of suffocation, no holding the breath, and no struggling. Dr. Noble had had a difficult case of tooth extraction—that of a young man about 25 years of age; oxygen was given, but he commenced to retch directly the face-piece was applied. About a week afterwards he was given pure gas, but he commenced to retch before anæsthesia was produced. A third time gas was given by Paterson's method, but again he vomited. The dentist being hindered in his work somnoform was tried. It was taken well and anæsthesia was produced which lasted for three minutes with no bad after-effects. With regard to after-sickness it was not usual when the patient had been prepared, but many went to the hospital not knowing that an anæsthetic would be used and, of course, they vomited if they had previously taken food

Dr A H BOLYE remarked that the rapid action of the drug was a great advantage He had tried it for the removal of tonsils and adenoids, but had found that it was hardly sufficiently anæsthetic in its action for both together He had had some experience in giving it in longer cases lasting from 10 to 18 minutes In two of these cases in which the patients became very pale and collapsed the anæsthetic was stopped and they then vomited and quickly returned to consciousness In the drinking type there was considerable struggling In one case that of a man with abscesses on both hands to whom he gave somnoform the hands and legs were moving during the whole time and the operator had great difficulty

The report of the council and that of the treasurer were then read

A vote of thanks to the retiring officers was proposed by Dr DUDLEY BUXTON who in a eulogistic speech in the name of the society, thanked Mr George Ea tes for his untiring work for the society during the last five years This was seconded by Dr H LOW The following officers for the next session were then elected President Mr C Carter Braine, vice president Dr J F W Silk, honorary treasurer Dr R J Probyn Williams, members of council, Mr Walter Tyrrell, Dr Flux and Dr C J Woollett, honorary secretaries Mr Harvey Hilliard and Dr McCardie, and auditors, Dr J Blumfeld and Dr Ada M Browne

WEST KENT MEDICO CHIRURGICAL SOCIETY

The Principles of Dietetics

A MEETING of this society was held on April 3rd Dr GEORGE HERSCHELL, the President being in the chair

Dr ROBERT HUTCHISON opened a discussion on the Principles of Dietetics with an address which is published in full in this issue of THE LANCET

The PRESIDENT said that as regarded his own part in the discussion that evening he should like to say a few words upon the principles which guided them in the selection of appropriate diet for some of the commoner forms of affections of the stomach He would speak first of morbid sensibility of the stomach This might be met with in two distinct conditions (1) as a purely functional disorder, and (2) as a symptom of some anatomical or structural disease of the stomach The diet was essentially different in each Whilst in functional hyperæsthesia of the stomach they were unable to lay down any hard and fast rule as the stomach reaction to food was not constant, on the other hand in hyperæsthesia due to a distinct anatomical disease the irritability produced by food always varied in direct ratio to its digestibility In the latter case they would find that if alcohol, acids, condiments sweets peptones, strong soups, and meat extracts were excluded and the food in a finely divided state was given not too hot and not too cold the symptoms of the patient would be invariably alleviated Such a diet was therefore indicated to be gradually increased as the patient recovered In the hyperæsthesia of a functional nature they would not be so fortunate, they would search in vain for a diet on which the patient could live without pain, in some cases the stomach was even conscious of the contact of its own walls and was painful when empty The rule which should guide them then, in prescribing a diet for such cases was to cease to attempt to find a diet upon which the patient could live without pain but to put him on one which theoretically should not disagree, and ignore the sensations which followed the meal Of course if any article of food was found which manifestly caused distress either it should be omitted from the dietary or, better still administered in a finely divided state and in smaller quantity Most sufferers from gastric neurasthenia were starving themselves and it must be borne in mind that if the daily food was reduced below the limits required for the maintenance of the equilibrium of the body the stomach would participate in the general tissue starvation and its condition of irritable weakness would be perpetuated. Under the heading of conditions associated with excess of hydrochloric acid in the stomach they had ulcer, functional hyperchlorhydria, and organic hyperchlorhydria due to hypersthenic glandular gastritis—that was to say, a form of chronic gastritis associated with increase and proliferation of the secreting glands of the stomach In dieting the members of this group they were guided by the main principle to provide a food as unirritating and indifferent in its local action as possible, whilst at the same time having as high a combining power for hydrochloric acid This was effected by minute subdivision elimination of any particles which might be insoluble the omission of condiments and the reduction of starch to a minimum As Dr Hutchison had said the ranks of specialist physicians who devoted attention to affections of the stomach were split up into three groups (1) those who favoured an albuminous diet; (2) those who believed that meat, although having a high combining power for hydrochloric acid, yet from its stimulating action would eventually lead to a larger secretion and therefore give starch, and (3) those who favoured a mixed diet As a matter of fact, the fact was lost sight of that the digestion of no other kind of food left so much hydrochloric acid free in the stomach as starch and the stimulating action of meat upon the gastric secretion varied very much according to the manner in which it was given Beef steak grilled and eaten in the ordinary way produced a far greater stimulating action than when scraped free from fat and fibre made into small cakes, and slightly grilled Functional and organic hyperchlorhydria should both be treated with the same articles of diet prepared in the same manner, but an important difference existed as to the best arrangement of meals in the two conditions In organic affections it was not so necessary to secure immunity from mechanical irritation and they could therefore give out food in three large meals a day The great advantage would be that whilst the stimulating property of the meal would not be sensibly increased, there would be a larger bulk available for mopping up the hydrochloric acid and less free acid would be left at the close of the meal With ulcer and organic hyperchlorhydria as they wished to reduce mechanical as well as chemical irritation to a minimum they should give several small meals of bland, finely divided food with as high combining power for hydrochloric acid as possible As regards subacidity, in cases where the secretion of hydrochloric acid in the stomach was in defect it was obvious that the greater part of the digestive work must fall upon the intestines The first main fact which would strike them was that there being deficiency or absence of acid in the stomach the digestion of starch begun in the mouth would not be inhibited in the stomach They might therefore, with confidence increase the amount of starchy food to make up for the defective digestion of proteids in the stomach The observation of the cases in which total extirpation of the stomach had been performed showed that an ordinary mixed diet need not be departed from provided that eggs, which were likely to undergo fermentation in the intestines, were excluded and the food was given in a fine state of subdivision In the dieting of the motor weaknesses of the stomach in my-

— whether or not

If such was

might employ

the muscular

layer and helping to restore the contractility If, on the other hand the stomach was irritable as well as weak the food must be bland, unirritating and finely divided In all cases it was best to limit the amount of fluid taken during the meal and to let most of the drinking be done about an hour before In severer cases they might have to suspend for a time nearly all liquid by the mouth and to give it in t

The condition of gastric f

in the food eaten or fr

When arising from the latter cause they should always commence treatment by ascertaining that the mouth and gums were free from pyorrhœa alveolaris It had always been a source of wonder to him why a medical man with a case of gastric fermentation washed out the stomach, eliminated all fermentable material from the food sterilised the water and milk which the patient took, and yet allowed him to go away without once looking into the mouth and examining into the state of the gums. In pyorrhœa the patient swallowed with every mouthful of food several minims of pus containing millions of micro-organisms and they could see what a futile and hopeless task it would be to try to stop the fermentation in the stomach when they were allowing the alien germs freely to enter it. The next thing to do was to lavage the stomach. Then they could put the patient upon a diet consisting of meat, gelatin, and dextrinised bread. Green vegetables, fats, starch, sweets, and fruit were excluded, but these might be gradually added to the diet as improvement took place. In very bad cases it was a good plan to abandon feeding by the mouth entirely for a few days, devoting the time to daily lavage and rectal feeding.

Dr. LEONARD LL. B. WILLIAMS proposed a vote of thanks to Dr. Hutchison and said that he would like to add his thanks to those of the President for the very complete and suggestive survey of a difficult subject to which Dr. Hutchison had treated them. The question of diet in nervous disease upon which he had been asked to speak might be summed up in the advice to avoid stimulating foods and stimulating liquors. Dr. Hutchison had not gone into the very important question of alcohol, a question round which many nervous disorders might be said to revolve, but it nevertheless seemed impossible to exclude it from the present consideration. The power of taking alcohol with impunity might be, and to some extent certainly was, an individual matter; but it was also to an extent too little appreciated a climatic matter. The greatest consumers of whisky in the world were the Scotch and yet the two diseases which they were accustomed to regard as the classical examples of the consequences of spirit-drinking—namely, alcoholic peripheral neuritis and hepatic cirrhosis—were so uncommon in Scotland as to be considered rarities. The Scotch were, in fact, able to indulge in ardent spirits with an impunity which to us seemed very astonishing. He would not go so far as to say that the element of climate offered the whole solution to this problem, but he thought that the facts pointed very strongly to the advisability of taking some notice of local customs in the matter of alcoholic drinks, so that if the Scot stuck to his whisky the Englishman would be well advised in being faithful to his beer, the Devonian to his cider, and so on. He deprecated very strongly indeed the fashion which had grown up of late among medical men of advising their patients to drink whisky in lieu of wine or beer. Spirits led much more readily to habits of intemperance than did either beer or wine and the ease with which it was obtained made whisky a great danger in this direction. He though that very grave responsibility rested upon any man who recommended whisky to his patients, especially if those patients were females.

Dr. MORGAN DOCKRELL considered that the theory that dyspepsia was the cause of rosacea and acne was a mistaken one. Acne was due to blocking of follicles and diet had nothing to do with it. In lupus erythematosus diet was important, as it was necessary to get rid of uric acid. It was important to know how far urticaria required dieting.

Mr. CHISHOLM WILLIAMS spoke on the subject of diet in relation to obesity He had tried every known remedy for obesity but without result. On several occasions he had found that a change of diet led to an attack of influenza.

Dr. R. E. SCHOLEFIELD said that the same diseases were found in various countries with different diets. This made him sceptical as to the influence of diet. It was useless to argue from the diseases of the Hindoo to those of the Esquimaux and the Scot. He still stuck to a diet of pure sterilised milk for infants and his success had been surprising. The next best diet was egg albumin and water. Occasionally obesity was found even in infants. This was often due to anæmia and might be cured by iron.

Dr. T. C. MEGGISON asked for suggestions with regard to diet in anæmia.

Dr. HUTCHISON, in replying, said that he was in accord with Dr. Leonard Williams that alcohol and tea should be avoided in nervous diseases. The mode of drinking might account for the fact of there being more cirrhosis of the liver in England than in Scotland. The Scot usually drank on Saturday night only while the Englishman was always soaking in beer. He did not find Haig's diet useful in gout. He did not think that diet was of much importance in anæmia, but many girls suffered from anæmia because they did not eat enough meat.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on April 2nd, Dr. W. Winslow Hall, the President, being in the chair.—Dr. L. G. Guthrie read a taper on Some Ancient Remedies and on Gideon Harvey, a seventeenth-century physician. He commented briefly on the position of medicine in the latter half of the seventeenth century, showing that the progress of scientific treatment was impeded by ignorance of pathology, by neglect to make use of the great anatomical discoveries of the age for practical purposes, by superstition and tradition in the use of the remedies employed, by multiplicity of medicaments and ignorance of their physiological action, and by abuse of venesection, vesication, issue-making, sweating, purging, emesis, and salivation. Valvular heart disease, cardiac and renal dropsy, and all forms of nephritis, except that dependent on calculus, were unrecognised. Biliary colic, or at all events the jaundice associated with it, was regarded by Sydenham as a manifestation of hysteria. The urine in diabetes mellitus was known to be sweet, but no importance was attached to the fact. Willis thought that all diseases were due to alterations in the crasis of the blood, which he held to be composed of spirits, sulphur, salts, earth, and water. In fevers he believed that the spirits literally boiled, and the sulphur took fire and smouldered. Treatment consisted in attempting to drive noxious substances out of the blood by the methods mentioned above. Historical instances were given in which death was hastened by excessive bleeding and purging, as in the case of Charles II. Gideon Harvey, physician to Charles II., rendered considerable service to medicine by counselling the use of a few remedies the action of which was understood. He showed that the 60 or 70 ingredients of those very popular medicines Venice treacle and mithridate were mostly incompatible and that these compounds owed their virtue solely to the opium which they contained. He parodied Sydenham's famous "expectant attitude" towards diseases with which he was unfamiliar, in a witty little book called "The Art of Curing Disease by Expectation." Gideon Harvey's services to medicine never met with the recognition which they deserved, partly on account of his bitter hostility towards all his contemporaries, and towards the College of Physicians in particular, and partly on account of his inveterate habit of hinting in all his works that he possessed secret remedies and specifics against all diseases. But the pharmacopœias published after his day show that his views were tacitly accepted, as most of the loathsome and absurd preparations which he condemned were left out.—Mr. Raymond Johnson read a paper on Some Mistakes in the Diagnosis of Malignant Disease. He pointed out how mistakes in diagnosis were often due to the primary tumour being overlooked while a symptom caused by a secondary deposit was regarded as the essential disease. In illustration of this reference was made to the case of a woman who came under treatment for almost symmetrical paralysis and muscular atrophy in the upper limbs. The nature of the case was altogether doubtful until a small hard carcinomatous nodule was accidentally discovered in one breast. The necropsy revealed widely disseminated secondary growths, the muscular atrophy being caused by a deposit in the spine in which nerve roots supplying the brachial plexus were involved. Special attention was directed to secondary deposit of cancer in the bones, for if the existence of the primary tumour was unrecognised a secondary cancer might be easily mistaken for a primary sarcoma and possibly amputation of the limb might be performed before the mistake was detected. The diagnosis of malignant disease of the large intestine was not infrequently complicated by the occurrence of a large abscess in connexion with the growth; the abscess might be diagnosed while the tumour causing it was overlooked. Lastly Mr. Johnson referred to the many difficulties met with in the diagnosis of retro-peritoneal sarcoma. A case was mentioned in which an exploratory abdominal section performed on a young man revealed the presence of a large retro-peritoneal tumour having the characters of a soft hæmorrhagic sarcoma. However, a history of epistaxis was obtained and in early life the patient was said to have had an attack of "blood in the joints." This suggested the possibility of an extravasation of blood occurring in a "bleeder." The outcome of the case supported this view. For many months altered blood oozed from an opening in the middle of the abdominal incision, and the tumour gradually completely disappeared. Four years later the patient was in perfect health.—Dr. James Taylor said that he himself knew of an instance similar to the one mentioned by Mr. Johnson, in which the patient, whose case at one time was supposed certainly to be fatal, was now absolutely well. On the other hand, cases unfortunately occurred in which the patient, supposed to be suffering from functional disorder only, ultimately died from malignant disease.—Mr. J. D. Malcolm and Dr. Marmaduke Prickett also took part in the discussion.

SOCIETY FOR THE STUDY OF INEBRIETY—The last quarterly meeting of this society was held on April 21st, the *President, Dr Harry Campbell*, being in the chair —The President delivered his annual address on the Study of Inebriety a Retrospect and a Forecast The object of the society, he said, was the study of inebriety in all its forms—not only the inebriety produced by alcohol, but also the various forms of drug inebriety, such as those produced by opium, cocaine, chloral, and sulphonal, as well as by tobacco, tea, and coffee He pointed out that caffeine, the active ingredient of tea and coffee, was a vegetable waste product, an excrementitious substance allied to the waste products of the animal organism (urea and uric acid), that it was excreted as such by the kidneys and might thus in course of time predispose them to disease Caffeine had, moreover, a powerful action on the heart and blood-vessels, as well as upon the nervous system, and he raised the question whether it was wise to administer this drug as a matter of routine to children He attributed much of the nervousness not only among adults, but among children, especially the children of the poor, to the practice of excessive tea drinking He asked the question why it was so difficult to get a good cup of coffee in this country Many of the poor had never tasted the pure article Tobacco inebriety was a subject which just now especially claimed attention He had over and over again seen the nervous system shattered by excessive smoking The practice of cigarette smoking among boys had reached dangerous proportions and needed legislative interference He had little sympathy with the superlative fear, prevailing among many of interfering in the slightest degree with individual liberty, that bogey would vanish with increasing social enlightenment Let the individual have all the liberty which he craved to do good but do not let him have a free hand, above all before he arrives at years of "discretion," to injure himself and thus indirectly the State He pointed out that the ill effects of alcoholic drinks were largely due, not to the alcohol which they contained, but to foreign substances such as arsenic and lead, as well as to deliberate adulterations If people would drink alcohol steps should be taken to see that the community was provided with an unadulterated article, especially when that community spent something like £150 000,000 annually on its drink bill Much inebriety of all sorts was induced by advertised *nostrums* One had made thousands of chloral drunkards All owners of nostrums should be compelled to publish with each sample an analysis of its contents To allow this trading in secret remedies was unworthy of an enlightened people and an insult to that large army of scientific workers, all over the world, who were earnestly, patiently, and laboriously seeking to fight disease content to get their reward, not in financial advancement, but in the knowledge of good work done —The Honorary Secretary read for Mr Arthur Sherwell a paper on Inebriety in Scotland, in which, as the result of an extensive statistical investigation regarding the returns as to the consumption of alcohol prison records reports of mental cases, and official figures of the mortality from intemperance it was shown that inebriety was on the increase and particularly in female subjects —A large number of members and associates took part in the discussion.

LARYNGOLOGICAL SOCIETY OF LONDON—A meeting of this society was held on April 3rd, Dr J Dundas Grant, Vice President, being in the chair —Dr W H Kelson showed a case of Infiltration of the Epiglottis Arytenoepiglottic Folds, Arytenoids, and Right Ventricular Band, in a man, aged 55 years, probably tuberculous, though no tubercle bacilli could be found in the sputa and there was no sign of pulmonary lesion —Dr E Furniss Potter showed a case of Singer's Nodule in a man, aged 41 years affecting the left vocal cord.—Dr H Tilley showed a case illustrating Radical Cure (by obliteration) of Bilateral Maxillary Sinus Empyema. Large openings were made in the canine fossæ, the lining membrane was scraped, and the cavities were packed for two days, after which nothing further was done except to syringe out twice daily and carefully to dry the antra. It was shown that the cavities were now practically filled with granulation tissue, it being only just possible to pass a probe upwards through the fistulous track through the original opening in the canine fossa —The case was discussed by Dr G W Hill Dr F de Havilland Hall, Dr H W Fitzgerald Powell, Mr E B Waggett, Dr H Lambert Lack, Dr R H Scanes Spicer, and Dr Dundas Grant —Dr L H Pegler showed a case of *Clonic Spasm* of the Muscles of the Palate and Pharynx causing Entotic Tinnitus —Dr J [illegible] he Pharynx and Larynx [illegible] —Mr L A Lawrence [illegible] soft Palate —Mr F H Westmacott showed a *specimen and section* of Acute Tuberculosis of the Left Tonsil from a man, aged 32 years There was no *family history or evidence of* tubercle [illegible] spread to the soft palate [illegible] ealy, I M S, showed a mic[illegible] Psorospermosis of the Mu[illegible] Membrane of the Septum Nasi He had been unable to find any previous record of *this disease* having occurred in the nose The origin in this instance was attributed to direct infection *from raw hides* among which the patient had been working —Mr R S *Charsley* showed a case of Polypi of the Maxillary Antrum —Mr Waggett showed (1) A case of Sphenoidal Sinus Suppuration in which the anterior wall had been removed with an instrument *designed* by Dr Lack, and (2) a case and specimen of Papilloma *of* the Larynx.—Dr Dundas Grant showed (1) *A case of Immobility* of the Left Cord attributable (?) to bronchocele, in which resection and extirpation of the isthmus and *left lobe had been performed* (Dr de Havilland Hall *remarked that there* were more thickening and enlargement of the left arytenoid than were accounted for by pressure *on the left recurrent* [illegible] her than a paralytic con[illegible] Recurrent *and the Left* [illegible] woman, and (3) a case [illegible] 'hs' duration in a man, aged 50 years, probably epithelioma —Dr H J *Davis* showed a man, aged 27 years, with a swelling on the right side of the larynx causing partial occlusion, and with a history of hoarseness for the last six years —The case was discussed by Sir Felix Semon, Mr H T Butlin, and *Mr* Waggett —Dr V H Wyatt Wingrave showed a case of Rapid Destruction of the Nasal Septum —Dr H Burt showed a case of Goitre with Early Exophthalmos

HUNTERIAN SOCIETY—A pathological *evening* of this society was held on March 25th, the President, Dr Stephen H Appleford, being in the chair —Dr J W M Ettles showed a case of Blepharo spasm without Ocular Lesion —Mr T Horrocks Openshaw, C M G, showed a specimen of a Section through the Pelvis of a patient the subject of congenital hip-joint disease This specimen showed clearly that it was impossible in some cases to replace the head of the femur in the acetabulum by manipulation The opening of the latter was seen to be much too small to admit the head of the femur —Dr W H Kelson showed a specimen and slide exhibiting Extensive Ulceration of the Larynx and Œsophagus in a woman, due to epithelioma.—Dr L A. Smith showed a specimen of a Large Kidney which on section proved to be made up of a number of small cysts with scarcely any renal substance remaining The fluid found in them was identical with that found in ovarian cysts and there was no evidence of duct obstruction —Dr W A Milligan showed two microscopic specimens (1) A specimen from a case of Carcinoma of the Stomach, in which the [illegible] ndication of such mischief (2) [illegible] Uterus from a woman, aged 63 [illegible] carcinoma. There was a history of only a few weeks At the operation the entrance of the dilator was prevented owing to blockage at the internal os, but on pressure the dilator was introduced and on withdrawal a copious flow of pus ensued A condition of pyometra had been set up by rapidly growing carcinoma.—Dr E W Goodall showed the fauces, larynx, and œsophagus from a case of Diphtheria. The patient was a boy, aged four and a half years who w[illegible] on March 22nd, 1903 on [illegible] theria which proved fata[illegible] post mortem examination there were two or three subcutaneous hæmorrhages on the legs and many subcutaneous hæmorrhages in the stomach. There was much membrane on the soft palate and tonsils and some in the larynx. The lower two inches of the œsophagus were covered with membrane, but there was none in the stomach. The specimen was shown on account of the rarity of membrane in the œsophagus —Sir Hugh R Beevor sent a specimen, which was shown by the secretary, of Syphilitic Liver taken from a girl, aged 16 years The specimen was indistinguishable at first sight as a liver There had been signs of hereditary syphilis present.—Mr. F. Gordon Brown exhibited an aorta which had been transfixed by a stab from a sharp knife which had penetrated the sternum. The point of interest in the case was that the walls of the aorta had been pushed in front of the knife for a certain distance before the cut was made so that the incision was not linear, and, like most of these fatal stabbing cases, both walls of the vessel were perforated. Death had been instantaneous.

FORFARSHIRE MEDICAL ASSOCIATION.—The sixth ordinary meeting of this society was held in the University College, Dundee, on April 3rd, Dr. W. Graham Campbell being in the chair.—Mr. D. M. Greig showed among other cases a man, aged 38 years, after primary amputation of the entire upper extremity including the scapula and outer two-thirds of the clavicle, necessitated by a severe laceration of the limb with great destruction of skin. Mr. Greig attributed the per primam healing to the patient's having had for the six days following the operation a daily injection of ten cubic centimetres of anti-streptococcic serum. He pointed out that the leaving of the inner third of the clavicle with the attachment of the clavicular portion of the sterno-mastoid muscle helped to retain the symmetry of the neck.—Professor D. MacEwan showed a Hydronephrotic Kidney removed by operation.—Dr. R Cochrane Buist read a paper on Puerperal Infection. After a sketch of the natural defences against infection he referred to the use of abdominal palpation and discussed the deleterious effects of intra-partum antiseptic douching. Under the head of therapy he urged the use of ergot, the bad results of routine curettage, and the dangers of the antiseptic intra-uterine douche, especially with mercurials. He recommended solutions of salt or sodium bicarbonate followed by strong alcohol. In the general treatment he mentioned the failure of serum and the mischief of extreme alcoholisation and while insisting on the fallacy of reasoning from individual cases considered the reports of good results obtained from the use of remedial measures such as antipyrin, silver, and artefact abscess.—Professor J. A. C. Kynoch in his remarks pointed to the necessity for absolute care in the cleansing of the hands He agreed that abdominal palpation was useful, but it did not give all the information that the vaginal examination gave. He considered that the danger of mercurial poisoning after treating with mercurial lotion was no greater than that after other antiseptics. It was due to mercurial douching that maternity hospitals, formerly dangerous institutions, were now relatively free from danger —Professor C. R. Marshall strongly emphasised the great danger in douching such cases with perchloride of mercury lotion.

PATHOLOGICAL AND CLINICAL SOCIETY OF GLASGOW.—The seventh ordinary meeting of this society was held on April 20th, Mr. A. E. Maylard, the President, being in the chair.—Dr. John Anderson showed as a fresh specimen a Brain in which an abscess in the Rolandic area had extended into the lateral ventricles. It was connected with a case of empyema.—Mr. J. Grant Andrew showed a boy who was operated on for Foreign Body in the Left Bronchus; removal was attempted by posterior bronchotomy through the pleural cavity.—An interesting discussion on the treatment followed, an expectant line being strongly advocated by Sir Hector C. Cameron.—Mr. Henry E. Clark exhibited (1) a Bladder showing Sacculation and Abscess Formation from a case of enlarged prostate, as well as the Kidneys from the same case; and (2) a Uterus the subject of Carcinoma of the Body removed by the para-vaginal method.—Mr. John H. Teacher reported on the intestinal concretion shown at the last meeting by Dr. J. Crawford Renton, which proved to be an oat-seed concretion (avenolith) and exhibited for comparison a number of specimens of similar concretions from the Hunterian Museum, University of Glasgow.—Dr. J. Kerr Love showed a series of stereoscopic photographs illustrative of the Anatomy of the Temporal Bone which were highly appreciated.—The following card specimens were shown by the President: Three sets of Gall-stones removed from the same case—(1) faceted stones from the gall-bladder; (2) one large corrugated stone impacted in the cystic duct; and (3) a similarly corrugated but smaller stone impacted in the common duct.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 1st, Mr. J. Mackie, the President, being in the chair.—Dr. Astley V. Clarke, the honorary secretary of the Leicester Medical Society, introduced the subject of the proposed incorporation of local medical societies with the British Medical Association and he urged that the Nottingham Medico-Chirurgical Society should consider it.—Mr. R. C. Chicken showed: (1) A young man with Partial Dislocation of the Spine in the Cervical Region (with a skiagram); and (2) a patient with Synovial Arthropathies.—Mr. Chicken then read a paper on Pseudo-hypertrophic Synovitis. He described a condition frequently met with in miners and others following laborious occupations in which the alar ligaments of the knee-joint, and more especially the internal, increased in size and thickness; during movement they became trapped between the articular surfaces, giving rise to symptoms closely resembling those caused by a loose cartilage. The exquisitely sensitive edge of the thickened synovial membrane could be felt plainly just in front of the internal lateral ligament, quite distinctive from a loose cartilage except in the very earliest stages. Excision of the affected membrane was the only radical cure.—Dr. T. A. Clinch read a short note on Bullæ, their Medico-legal Aspect.

WIGAN MEDICAL SOCIETY.—A meeting of this society was held on April 9th.—Dr. M. Benson, the President, read his presidential address on the Treatment of Disease in accordance with the Symptoms exhibited.—The paper was an interesting one and gave rise to a good discussion, the following members taking part in it: Mr. C. M. Brady, Mr. William Latham, Mr. J. H. Fletcher, Mr. L. Cooke, Mr. J. E Parker, Mr. G. H. Monks, J.P., Dr. R. P. White, and Dr. John Blair.—A cordial vote of thanks was passed to the President and he replied to the discussion.

Reviews and Notices of Books.

A System of Clinical Medicine, dealing with the Diagnosis, Prognosis, and Treatment of Disease, for Students and Practitioners. By THOMAS D. SAVILL, M.D. Lond., Physician to the West-End Hospital for Diseases of the Nervous System; Physician to St. John's Hospital for Diseases of the Skin, London; formerly Medical Superintendent of the Paddington Infirmary. Vol. I. Local Diseases and Microbic Disorders. London: J. and A. Churchill. 1903. Pp. 702. Price 12*s.* 6*d.*

IN writing a System of Clinical Medicine Dr. Savill has adopted a plan which we believe will be found to be of great assistance both to students and to practitioners. He has approached the subject from the standpoint of symptomatology. Especial stress is laid on regional anatomy and the localisation of symptoms, whilst morbid anatomy and pathology are made to take rather a subordinate position and are only referred to in their strictly practical bearings. Not that we approve in any way of the separation of clinical medicine and pathology—that would be a grave retrograde step; but there are so many excellent special treatises on morbid anatomy and pathology that a work on purely clinical medicine may be cordially welcomed.

A uniform plan has been adopted throughout the whole volume. The first chapter is preliminary and describes the examination of patients and indicates certain general principles underlying methods of observation, diagnosis, prognosis, and treatment. In the second chapter the physiognomy of disease is discussed. The succeeding chapters deal seriatim with the symptoms and signs referable to the several organs or anatomical regions of the body taken in the order in which they ordinarily are examined, the causes of those symptoms, and the diagnosis, prognosis, and treatment of the diseases to which they refer.

Each chapter is divided into three unequal parts. Part A treats of the symptoms which may indicate disease of the organ or region under discussion and the fallacies incidental to their detection and supplies an account of the various causes which may give rise to those symptoms. Part B deals with the physical signs of disease in that region and the various methods employed to elicit them. Part C, which constitutes the major portion of each chapter, is prefaced by a clinical classification of the various maladies affecting that region and a summary of the routine procedure to be adopted, and these are followed by a series of sections dealing with the several diseases arranged according to their clinical relationships. This scheme has been admirably carried out and for the most part Dr. Savill has been successful in producing a very useful and practical work. A captious critic might find fault with certain details and there are one or two points to which exception may well be taken, but regarded as a whole the book will prove a valuable one to those for whom it is intended.

As an example of the way in which the diseases of the various systems of the body are considered we will take Chapter VI. which is headed "The Lungs and Pleuræ." After a few introductory remarks Dr. Savill proceeds to "Part A, Symptomatology." The cardinal symptoms are described and differentiated, such as cough, breathlessness, expectoration, pain in the chest, and hæmoptysis. The remarks on those manifestations are full and the description is accurate. In Part B, which deals with Physical Examination, minute directions are given as to the examination of the lungs by means of inspection, mensuration, percussion, palpation, and auscultation. Of this part also we can speak in approving terms. Part C is headed "Diseases of the Lungs and Pleuræ, their Diagnosis, Prognosis, and Treatment." These diseases are divided into acute and chronic, and subdivisions are formed according as to whether the percussion note is unaltered or whether there is dulness or hyper-resonance; for clinical purposes this is a fair practical classification. Each disease is then considered separately, a diagnosis first being arrived at. For instance, under the division Acute Diseases we find a paragraph in italics: "I. The patient complains of a cough with frothy expectoration and his temperature is slightly elevated; there is no alteration in the percussion note, but on auscultating the chest loud rhonchi are heard. The disease is acute bronchitis." A detailed description of the symptoms, physical signs, differential diagnosis, prognosis and treatment follows. In the great majority of instances this plan answers well, but we have noted some exceptions. For instance: "III. The patient complains of breathlessness; on examining the chest dulness is found at one or both bases; and on auscultation fine crepitations are heard. The disease is pulmonary congestion or œdema." Pulmonary tuberculosis occasionally commences at the base of the lung and may give rise to the same symptom and physical signs; likewise, these signs are not infrequently met with after a subsidence of pleurisy with effusion. Neither of these conditions is mentioned in the text. These exceptions do not, however, alter the value of the general arrangement adopted by Dr. Savill. We commend the use of the italicised paragraphs which, standing at the head of each section dealing with a separate malady, emphasise the salient features by which a disease may be recognised and differentiated from others belonging to the same group. The paragraphs referred to are brief clinical definitions and they form, as Dr. Savill expresses it, "sign posts" or guides in the process of diagnosis.

Whilst the symptoms, diagnosis, and prognosis of each disease are fully and accurately described we cannot speak in such terms of the sections devoted to treatment. The remarks on this subject are vague and wanting in detail. Certain drugs are mentioned but the methods of administering them in different circumstances are not sufficiently fully stated, and in future editions of the work the sections dealing with therapeutics may with advantage be considerably amplified. We should mention, however, that at the end of the volume are a large number of useful formulæ for prescriptions. Another matter which we should like to see altered (it may be considered a trivial one) is the free use of contractions of words and phrases in which Dr. Savill indulges—such as "r" and "l" for right and left, "C.V.D." for cardiac valvular disease, and "R.M." for respiratory murmur. To most readers these contractions are objectionable and they serve no useful purpose. As we have already said, however, taking the book as a whole, we have formed a high opinion of Dr. Savill's work; we wish it the success that it deserves and look forward with interest to the publication of the second volume.

Diseases and Injuries of the Eye, with their Medical and Surgical Treatment. By GEORGE LAWSON, F.R.C.S. Eng., Consulting Surgeon to the Royal London Ophthalmic Hospital and to the Middlesex Hospital. Sixth edition, with 249 Illustrations. Revised and in great measure rewritten by ARNOLD LAWSON, F.R.C.S. Eng., Assistant Surgeon to the Royal London Ophthalmic Hospital. London: Smith, Elder, and Co. 1903. 8vo., pp. 587.

THIS volume contains the observations and experience of two generations. Mr. George Lawson, ophthalmic surgeon in ordinary to our late Queen, published many years ago a manual which on account of its accuracy, comprehensiveness, and brevity was very favourably received by the profession and especially by those who were, or had been, studying at the Royal London Ophthalmic Hospital. It ran through several editions. But as is usual with scientific works that have received frequent emendations, corrections, and additions, it required, in order that it might be brought up to the present state of our knowledge, complete recasting. This Mr. Arnold Lawson has set himself the task of accomplishing and we doubt not that it has been a labour of love. The book has been considerably enlarged and to a large extent re-written. Chapters on the Development of the Eye, the Pupil, the Affections of the Eye in Diseases of the Nervous System, and other subjects have been added and the general arrangement of the whole work has been remodelled. Many new woodcuts have been inserted and the majority of these are extremely well executed and instructive.

The feature of the treatise that will be most appreciated by the more advanced reader is the manner in which disputed points are discussed. Thus, in regard to sympathetic ophthalmia the authors observe that there is in general a well-marked distinction between sympathetic irritation and sympathetic ophthalmitis, though doubtless cases are occasionally met with in which long-standing sympathetic irritation may run into sympathetic ophthalmitis. The chief differences between the two conditions, it is pointed out, are first that in the former affection, notwithstanding frequent recurrences of inflammatory symptoms, no fibrinous effusions or disorganising changes of the different tissues of the sympathising eye take place, and, secondly, that the excision of the originally injured eye at once arrests the disease. In considering sympathetic ophthalmitis the arguments in favour of a specific origin and those against that view are concisely given. In describing the operation for the extraction of cataract, the three-millimetre flap operation, the cut corresponding to the upper margin of the cornea, is recommended. The steps of the operation in general use are followed and in speaking of the needling of secondary cataract or of capsular opacities it is justly remarked of this proceeding, so lightly undertaken by the inexperienced operator, that the risk which attaches to it is almost as great as that attending the extraction of an uncomplicated cataract and it is proposed that if a patient can read No. 6 of Jaeger's test-types he, as well as the surgeon, should be satisfied; with this dictum we are thoroughly in accord. Nothing is more disappointing to the patient who has passed through the anxiety attendant upon the first operation, and who has been told that the secondary operation is a mere trifle, than to find that its result, unless an instant sclerotomy or iridectomy is performed, has been to destroy all the good effects of the surgeon's skill and his own patience; the benefit which he had fully expected would result in the permanent recovery of vision is lost. A satisfactory account is given of granular conjunctivitis or trachoma. The authors regard this affection as presenting two forms, the acute and the chronic. They consider it to be contagious and to be distinguished from follicular conjunctivitis by the circumstance that it always affects the palpebral conjunctiva; they say that its intractable nature renders strong measures indispensable and these measures are given in full detail.

The chapters on the Choroid and Retina with the accompanying illustrations show what great advances in the diagnosis of the diseases affecting the interior of the globe have been made since the introduction of the ophthalmoscope, though, unfortunately, with but little improvement in the treatment. In the chapter on Diseases of the Lacrymal Apparatus some judicious remarks are made on the application of probes and the objections which exist to the employment of very large ones are clearly stated.

An interesting chapter is devoted to the method at present in use for the localisation of foreign bodies in the eye by the x rays and a description is given of Mackenzie Davidson's apparatus with cross threads. A drawing is also introduced of the powerful magnet employed by Haab. By the precise localisation of the foreign body in the eye with the subsequent employment of the magnet excellent results have been obtained. At the Royal London Ophthalmic Hospital Mr. A. F. MacCallan finds, on a review of all the cases in which these means have been used, that 58 per cent. of injured eyes have been saved.

Much pains have been taken with the chapter on the Affections of the Extrinsic Ocular Muscles and the action of these muscles and the results of their paralysis are very clearly described

We must not omit to refer to the index, the compiling of which doubtless involved considerable labour. It not only contains an unusually large number of entries but it gives many cross references. Thus, under the head "Ciliary Body" there are no less than nine primary references—viz., to the anatomy of this region, to ciliary asthenopia, carcinoma, cysts, diseases, injuries, inflammation, tumours, and wounds of this region, with cross references to iris, ciliary body, and cyclitis.

In conclusion, we have no hesitation in expressing the opinion that the treatise is a thoroughly trustworthy guide to the student and the practitioner and a valuable addition to the ophthalmological literature of this country.

The Uniform System of Accounts for Hospitals, Charities, Missions, and Public Institutions. By Sir HENRY BURDETT, K.C.B. London: The Scientific Press, Limited. 1903. 9½ × 6 inches. Pp. x., 103. Price 4*s.* net.

SINCE "The Uniform System of Accounts, Audit, and Tender" was first issued in 1893, not only the London hospitals and public institutions, but a large number of charities and smaller institutions of a similar character throughout the kingdom and in some British colonies have found it desirable to avail themselves of the methods inculcated. Every foundation dependent for its income upon voluntary contributions may find among its supporters benevolent persons who will be moved to give without exact inquiry into the details of its expenditure, but at the same time it will have among those who sympathise with its work a far greater and more important section of the public who will wish to know its financial position and to be satisfied that their money is carefully and economically dealt with before they appear among its subscribers. In order that these may be able easily to obtain the necessary information it is clear that the public institution desirous of their support must not only keep its accounts accurately, but must so keep them that they may be readily and lucidly summarised for the benefit of those who have no time to study them in a more voluminous form. Uniformity of system renders comparison easy, and the institution that so offers its accounts that they can be fully understood and compared with those of kindred establishments will not suffer by its candour. It is hardly necessary to refer to the admirable effect which the introduction of a simple and universal system of accounts has had in London. It has, in particular, rendered possible the working of the Hospital Sunday Fund, which, in order to be able to test efficiency, has exacted uniformity from the hospitals to which it has made distribution and has thus paved the way for the effective working of the other great funds the committees of which have followed in its footsteps. The present volume amplifies and enlarges the former guides which have been published to the same end and its careful study is to be commended to all those interested in the maintenance of hospitals, cottage hospitals, orphanages, and other institutions of corresponding character whether great or small in which the system advocated has not yet been introduced. Many hospitals and infirmaries in country districts have upon their governing bodies gentlemen and ladies whose concern is with the business and financial, rather than with the medical, conduct of charities which may not be over-flourishing. To such as these Sir Henry Burdett's latest issue should prove a valuable aid. It may be added that the books of account the use of which is recommended are now obtainable from the Scientific Press, Limited, so that the expensive necessity of having books ruled and printed to suit the exigencies of hospital work may be avoided.

LIBRARY TABLE.

Inoculation against Malaria. By Dr. PHILALETHES KUHN, Staff Surgeon to the Imperial Troops of the South-West Africa Protectorate. Translated by H. A. NESBITT, M.A. London: H. K. Lewis. 1902. Pp. 32. Price 2*s.*—In this pamphlet Dr. Kuhn gives a short description of observations which he has made during a residence of five years in German South-West Africa in regard to a serum for inoculation against malaria. He first gives a description of a malady known as "horse-sickness," an acutely infectious disease affecting horses and mules in South Africa. He states that he has discovered a serum against horse-sickness which possesses the power not only of curing the disease in affected animals, but also of bestowing temporary immunity against future attacks. Dr. Kuhn maintains that malaria and horse-sickness have many points in common, and acting on this theory he has inoculated patients suffering from malaria with the serum obtained from horses suffering from horse-sickness. The results so far obtained are not very convincing but are sufficiently encouraging to merit a further trial of the treatment. Dr. Kuhn found that if the inoculation was made during a paroxysm of malaria the attack was relieved and also a certain immunity was conferred against future attacks. Unfortunately, owing to the vicissitudes and undeveloped condition of the colony it was not possible to conduct continuous observations on patients who had been inoculated, so that their subsequent history could not be obtained. Dr. Kuhn promises to publish his further experiences and it will be then more easy to judge as to the value of the serum which he has employed.

Colonial and Camp Sanitation. By G. V. POORE, M.D., F.R.C.P. Lond. London: Longmans. 1903. Pp. 43. Price 2*s.*—Dr. Poore is well known as an ardent advocate of common-sense sanitation, and in the little book before us, the contents of which are reprinted from his Milroy Lectures and "The Dwelling House," he has gathered together "matter which is applicable to colonial and camp sanitation." Dr. Poore writes as one who has tried the measures which he advocates and has found them successful. They do not of course pretend to be applicable to the town-dweller but we advise those who live in the country to give Dr.

Poore's methods a trial. When carried out with strict attention to detail their results seem to be admirable.

JOURNALS AND MAGAZINES.

The Practitioner.—The April number of this journal is not so well provided with good original articles as is usually the case. It contains, however, some careful records of interesting and instructive cases. Dr. S. Vere Pearson gives a thoughtful consideration of the differential points in diagnosis between croupous and catarrhal pneumonia in infants—conditions in which the prognosis is so dissimilar that accurate diagnosis is of the very highest importance. Mr. D. J. Armour in a review of recent surgery of the nervous system goes thoroughly into the question of the surgical measures for the cure of epilepsy and gives Sir Victor Horsley's valuable and concisely formulated views on the subject. Mr. Malcolm A. Morris, the late editor of the *Practitioner*, writes upon the light treatment of lupus and other skin diseases and amongst other articles are contributions from Dr. John Philips and Dr. Nathan Raw.

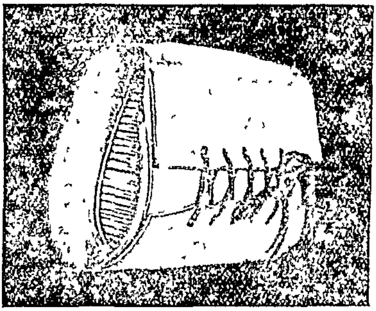
South African Medical Record. March, 1903. Price 1*s.*—We have received the first monthly number of this journal which is devoted to the interests of the medical profession in South Africa. Mr. S. W. F. Richardson contributes some remarks upon the Surgical Treatment of Appendicitis; Dr. G. A. Casalis deals with the subject of Curettage; Dr. W. E. Smith writes some notes on the Symptoms and Diagnosis of Iritis; and Dr. E. Sinclair Stevenson has a paper on Some Obscure Cases in Abdominal Surgery. Having regard to the non-success of some previous ventures in medical journalism in South Africa the editor is to be congratulated on his courage in starting a new journal. We hope his efforts will be rewarded with success.

Flora et Sylva. No. 1. Edited by W. ROBINSON. London: 17, Furnival-street, Holborn. Price 2*s.* 6*d.* net.—This is the first number of a new monthly review "for lovers of landscape, tree or flower," and the editor is one well qualified for his work, for he is the author of that admirable book, "The English Flower Garden." The review is beautifully printed on paper which appears to be hand-made and most probably is so. The type is a well-cut "old-face" (in connexion with which the printers need reminding that the character "*b*" is another form of the more usual "*h*" and should not be confused with the character "*b*," as has been done), while the illustrations are admirable. Some of them are coloured and are notable instances of colour printing, others are actually woodcuts, and two which are relegated to a kind of appendix are process blocks. Everyone who loves a garden and is fortunate enough to possess one should read this new review in which we are glad to see a paragraph in praise of woodlands.

New Inventions.

A MODIFICATION OF ALLIS'S ETHER INHALER.

I BEG to recommend to the notice of the readers of THE LANCET a very useful modification in the form of Allis's ether inhaler, made by Mr. Robert Henry Lavender, one of the secretarial staff of the Liverpool Royal Infirmary, and daily used throughout the surgical department of that institution. Hitherto the cage-like frame upon which is wound in and out a long strip of flannel or stockinette bandage to hold the anæsthetic liquid, has been covered up in a large rubber tube slipped over it but not easily moved off and on. To facilitate cleaning and the easy frequent removal of the rubber cover Mr. Lavender has had the latter constructed, not as a closed tube, but in the form of a sheet to lace on. The ends of the sheet overlap so as to be air-tight and are bound on the frame by lacing a couple of flaps attached to their outer side and provided with eyelets. The frame itself was many years ago improved by my colleague, Mr. F. T. Paul, who had it strongly made of wires attached at each end to an oval metal ring perforated with holes, into which the wires fit and are soldered in position. Thus made the frame can resist more than any pressure likely to be put upon it, and is a great improvement upon the form flimsily constructed of a mere sheet of metal perforated in slits and bent to the required form, but not rigid enough for the purpose.

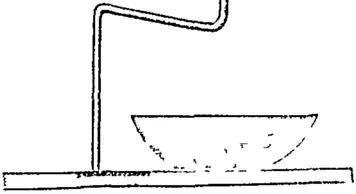


The inhaler is made for us by Messrs. Ewing and Co., Pembroke-place, Liverpool (adjacent to the hospital), and the accompanying illustration explains its details.

RUSHTON PARKER,
Professor of Surgery, University College, and Surgeon to the Royal Infirmary, Liverpool.
Liverpool.

IMPROVED LEG SUPPORT.

Apropos of the "Improved Leg Support" described by Dr. W. A. Carline in THE LANCET of April 4th, p. 974, perhaps the readers of THE LANCET may be interested in an apparatus devised by me for a similar purpose and now used in the out-patient department of Sir Patrick Dun's Hospital, Dublin. It consists simply of a light round iron bar bent in the manner shown in the illustration. One end bears a rest for the heel, the other being fixed to an oblong wooden base. This foot rest has the advantage that in cleansing the limb or applying lotion any superfluous fluid runs down to the most dependent point of the curve under which a receiver is placed. In practice it is found much more convenient than the old pattern, where the heel is supported right above the central pillar, along which fluid is liable to escape to the floor. Every part of the supported limb is accessible for dressing, bandaging, &c.



F. J. STRONG HEANEY, M.D. Dub., F.R.C.S. Irel.

THE LANCET.

LONDON: SATURDAY, APRIL 25, 1903.

The Fourteenth International Congress of Medicine.

THE proceedings of the Fourteenth International Congress of Medicine, which are under the patronage of his Royal and youthful Majesty KING ALFONSO of Spain, were inaugurated on Thursday last, April 23rd, and will, it is hoped, prove successful in every way. As we have before now said, we do not regard medical or other scientific congresses as holding out much prospect of advancement to our knowledge. The day is to some extent gone by when it is of the first importance that medical men should meet face to face to compare their views or to communicate their researches in respect of disease. A voluminous and, on the whole, a responsible and well-informed medical press in every country provides a medium for the dissemination of professional knowledge and this being the case no medical man is for the future likely to withhold from his brethren any valuable discovery in order that he may make an imposing pronouncement to them at an International Medical Congress. The official programme of the Madrid Congress has not yet reached us, the dilatoriness of the officials of the Congress in the matter, to which we have referred recently, being this week made the subject of comment by our special correspondent at Madrid who, however, acquits them of blame in the trying circumstances. We understand that the promised proceedings do not include any papers which record startling therapeutic or pathological advancement. This was the case at Moscow on the occasion of the twelfth International Medical Congress, where valuable contributions to medical and surgical knowledge were read in many sections but where no marked innovation of theory or practice was recorded. If, however, those of our countrymen who attend the International Medical Congress at Madrid do not come away with any new learning—and many will find attendance at a crowded congress in a foreign capital far from conducive to their learning anything at all in the nature of scientific facts—they cannot help acquiring much valuable knowledge of life in general and the *vita medica* in particular by their visit to Madrid. The sights, the customs, the social observances, and the methods of living, no less than the hospitals, the libraries, and the courteous personalities of their hosts, will all serve to stimulate new sensations, to arouse new ideas, and to provide food for pleasant reflection afterwards. The visitors will acquire standards of comparison which will reduce in our countrymen the predisposition to dogmatise with which as a nation we are reproached. This alone will be a gain of inestimable benefit to members of a profession where so much depends upon the capacity of an observer to take an all-round view of a situation. Our special correspondent's letters do not foreshadow any great scientific reputation for the Congress in Madrid. The arrangements of organisation were not ready when the day of the opening of the Congress arrived, but had more punctuality been observed the city could not have been transformed into an ideal centre for a meeting of persons of all nations and languages, for it is a national capital, not a cosmopolitan business centre. The limitations of Madrid, however, have their advantages. In London, Paris, or New York a man of any civilised nation can find persons, probably persons of his own nationality, able to minister to the wants peculiar to his nation. Therefore he does not live the life of London, Paris, or New York, but rather his own national life with certain economic or climatic modifications. In Madrid it is only open to do as Madrid does, and a first-hand acquaintance with a foreign city is thus thrust upon the traveller, unless he proposes to sojourn at one of a small group of hotels where the prices appear to have been driven up to extortion pitch by the reprehensible and unpatriotic methods of speculators. This makes for the expansion of view that is so healthy for all who are absorbed in the practice of medicine, and for this reason alone the British visitors to the Congress at Madrid cannot help benefiting by their experiences.

◆

The Increase of Cancer and Cancer Research.

EVER since the KING publicly expressed his desire that the deplorable increase of cancer prevailing throughout his dominions should receive the earnest notice of the medical profession with a view, if possible, to the discovery of means for its prevention, the subject has engaged a large share of public attention. This is as it should be, for in such matters as the prevention of widespread diseases the medical profession expects the coöperation of the laity; but we notice with regret that since the issue of a report on the prevalence of cancer by the Registrar-General of Ireland the English daily press has been literally inundated with correspondence dealing with the causes and cure of cancer and proving nothing but the ignorance or the indiscretion of the writers. The publication of such letters at the present time can only hinder the due consideration of a problem the solution of which we desire, on behalf of suffering thousands, to see accomplished at the earliest practicable date.

Whatever may be the true explanation of the fact, the national records of England contain abundant evidence that in recent years the deaths attributed, rightly or wrongly, to malignant disease have rapidly increased both absolutely and in relation to population. It is a disquieting fact that as time goes on cancer contributes a larger and larger share to the total mortality and this is particularly the case as regards persons who have passed the meridian of life. From the report of the Registrar-General of England for 1900, which is the latest issued up to the present time, we gather that among women who have attained their forty-fifth year of age, as well as among men ten years older, cancer exacts a yearly death-toll vastly heavier than that which is levied by that other national scourge, pulmonary tuberculosis. It would therefore appear from statistics that thousands of those whom medical science has in these more enlightened days enabled us to rescue from premature death from tuberculosis are doomed, after a respite of only a few years to fall victims to another and more terrible destroyer. For many years previous to the occasion on which the KING gave expression to the anxiety felt on this subject by the entire thinking portion of his people, the terrible suffering which cancer was known to inflict on the inhabitants of our own and other countries of Europe had attracted the sympathetic attention of the foremost minds in our profession; and although pathologists have not as yet discovered the organism, if such there be, the study of the life history of which will enable us to do for cancer that which is happily at the present time in course of accomplishment for tuberculosis, nevertheless the medical literature of the last decade clearly indicates that much useful though unobtrusive work has been done which it is reasonable to hope will one day bear good fruit. The work has hitherto been carried out for the most part by individuals privately and amid the cares and responsibilities of medical practice; consequently there has been little opportunity of comparison with the similar work of other observers. Indeed, until very recently there has existed in England no organisation by means of which scientific results in cancer research could be collated and tested or their merits discussed. We have always entertained the opinion that, if a problem of such acknowledged intricacy as the origin of cancer is to have a chance of ultimate solution, well-directed and perhaps long-continued pathological study must go hand-in-hand with systematic clinical observations. But in order that this may be achieved it is necessary, *in limine*, that some highly trained experts free from the distractions of medical practice should be able to devote themselves more or less exclusively to research. In this country this has been impracticable until recently from lack of the necessary funds. The scheme inaugurated last year under Royal patronage for the scientific investigation of malignant disease has unquestionably been started on right lines. Under the control of the Royal College of Physicians of London and the Royal College of Surgeons of England the arrangements have been settled by men of high professional standing as well as of acknowledged competence in their respective departments and, always provided that a continuance of the requisite financial and scientific support can be insured, we think that the public may await the issue with some confidence. But money, perhaps much money, may be wanted for some time to come and the active coöperation of our great hospitals is also earnestly desired. The results obtained by pathological laboratories endowed for research work alone may be jeopardised by the absence of sources from which to draw their necessary materials. This is a matter to which we alluded upon the institution of the Cancer Research Fund and which we wish to bring before the profession again, so that all necessary assistance of the work may be forthcoming. The central bureau of observation must be fed from outside sources.

A special report upon cancer in Ireland by Mr. R. E. MATHESON, Registrar-General of Ireland, to the publication of which in blue-book form we referred briefly in an annotation in THE LANCET of April 11th (p. 1047), deserves, and will doubtless receive, careful consideration from the Cancer Research Committee as well as from the medical profession. The report is based on a considerable number of facts and opinions—mainly on the latter—concerning the incidence of reported cases of the disease in various districts and upon specified sections of the population of Ireland. It is replete with the impressions of individuals on matters of heredity and also concerning the supposed infectiousness and transmissibility from person to person of the various forms of malignant disease. We have now before us all the information obtainable from official sources as to the enormous disparity which is alleged to exist between England and Ireland as regards the fatality of cancer. But although highly interesting in itself, this report cannot be regarded as of much scientific value, for the information relied upon for its compilation is in many instances derived from non-medical sources; nevertheless it shows unmistakeably that what is believed to be cancer is increasing in Ireland as in other parts of the United Kingdom and that certain specified areas of Ireland suffer more severely than others. Inasmuch as we are satisfied that the Cancer Research Committee has already commenced its labours in earnest, we refrain from discussing the many questions affecting the origin and spread of malignant disease which are touched upon in Mr. MATHESON'S report. Such matters form the special province of the Committee and discussion of them at large is to be deprecated just now as possibly hampering the Committee. Members of the medical profession, however, may greatly assist the Cancer Research Committee by communicating to Dr. E. F. BASHFORD, pathologist to the Committee, at the Examination Hall on the Victoria Embankment, any clinical or other definite information in their possession on the subject of cancer. We further trust that they will advise both their patients and such friends as they can influence to take the same course, and in any case to abstain from rushing into print with ill-considered suggestions for the cure or the treatment of cancer. The Cancer Research Committee can collate and appraise the value of all facts or theories submitted to its notice out of considerable experience and because of great opportunities of comparison. The lay press, not having these advantages, invariably selects for publication the silliest, because the most sensational, stories. The speculations which followed upon the publication of the blue-book upon cancer in Ireland and which were reproduced broadcast in the newspapers were most unfortunate. There will be a legitimate opportunity for ventilation of the subject after the Cancer Research Committee has issued a report. Meanwhile we think that it is only fair to the Committee to which the question has been authoritatively referred to await its conclusions. These conclusions can only take the form of *ad interim* suggestions and further discussion will naturally follow upon their publication.

◆

Our Food-Supply in Time of War.

A ROYAL Commission has been appointed to inquire into all the circumstances affecting the importation of food and the raw material of food into the United Kingdom in time of war. The amount of the reserves of such supplies existing in the country at any given period will also be considered by the Commission which will have to advise whether it is desirable to take any measures other than the maintenance of a strong fleet by which our food-supply can be made secure and both starvation and starvation prices can be avoided. The names of the Royal Commissioners, which have been brought prominently before our readers in the daily press, will be found in another column. They include H.R.H. the PRINCE OF WALES and 17 gentlemen who are all qualified in various and unmistakeable directions to take and to weigh evidence in this most difficult and sweeping inquiry; but the absence from the Commission of a medical man and a chemist cannot but strike our readers as most unfortunate. The extreme importance that is attached to the proceedings of the Commission is proved by the nomination of the Heir Apparent to the Crown as a member as well as by the inclusion of so many men of first-hand knowledge in matters of transport, of commerce, and of statistics. But while it is obvious that these matters are the ones which will first come under notice and on which most of the evidence will have to be taken, it is no less obvious that the whole inquiry is so vast in scope that the consideration of many side issues must be imported into it. Some of these, though narrow in themselves, may prove to be, when followed up, the deciding factors in the answers given upon the main questions, and we think it regrettable that the country will not have the advantage at the deliberations of the Commission of the presence of men with a scientific knowledge of food and food-stuffs, who can speak as to the physiological and dietetic values of food whether manufactured or in the raw and who can appreciate some of the chemical problems involved in the transport and storage of edible products.

The conditions of this country in time of war, it being assumed that the war is one against a first-class power, are singular, in fact, we believe they are unique in the history of the world. Our soil at the present moment does not produce enough food to supply half our population—pessimists have put the fraction that could be fed much lower in the frequent communications that have been made public upon the subject—although the populations of Ireland and Scotland are small in comparison with their acreage. Even to obtain from the soil of Great Britain an adequate food-supply for half the inhabitants an adjustment of work would be required amounting to a social revolution. This being so, and everyone knows that it is so, the conclusion is clear that unless we could import food during war we should starve in an appreciably short space of time. This means, again as everyone knows, that we must have a navy so preponderatingly strong and a mercantile marine so efficient that whatever the force brought against us we could always insure the transport of food. As to what the measure of strength or the standard of efficiency implied may be probably no authorities are agreed, but the Commission embraces among its *personnel* men of varying shades of political opinion who are eminently calculated to obtain full information on such points because of their intimate acquaintance with the problems of imperial defence. Of course the first questions to be decided in what bids fair to be an elaborate study of the nature and working of the import trade of this country will revolve round the methods which it is possible to employ, both in ordinary circumstances and in emergencies, for the transport of food and food-stuffs. Upon such questions as the number of battleships necessary, the strength of the mercantile marine to be maintained, and the countries to be looked upon as the probable ones for the obtaining of different food and food-stuffs the Royal Commissioners are well informed and will therefore be able to elicit and to appreciate the testimony of others. All the economic and statistical complications likely to be comprised in an inquiry that has for one of its objects the avoidance of violent fluctuations of price will receive the attention of a Commission numbering in its body experts in such directions. For the due consideration of none of these matters is a medical voice required so long as food and food-stuffs are regarded simply as food and food-stuffs, *always* wholesome and edible because *sometimes* capable of supporting life. But every medical man and every chemist knows that to appraise food and food-stuffs in this manner and to assume that all edible material will travel equally well, keep equally well, and produce equally nutritive results, is ridiculous. If the report of the Commission is to supply the country with sound suggestions as to the proper steps to be taken to secure an adequate food-supply in time of war it is necessary that the qualities of the food and food-stuffs, as well as the measures to be adopted to maintain them in conditions of wholesomeness, should come under some discussion. Who is to assist the Commissioners to ask pertinent questions when such matters are on the *tapis?*

We regard the appointment of this Royal Commission as a most important national event and we must not be understood as desiring to thrust medical men into places where their views are not of scientific value simply with the desire to exalt our own profession. We are perfectly aware that such members of the Commission as the PRINCE OF WALES, with the experiences of his grand tour fresh upon him; as Sir ALFRED BATEMAN, Comptroller-General of the Commercial, Labour, and Statistical Department of the Board of Trade; as Colonel MONTGOMERY, President of the Liverpool Corn Trade Association; as Mr. J. E. STREET, the chairman of Lloyd's; as Admiral NOEL, the Duke of SUTHERLAND, Sir J. COLOMB, and Mr. CHAPLIN, can speak with vastly more authority than any medical man upon the broad questions. But the Commission will require, or ought to require, accurate information from witnesses upon details no less than upon broad questions, and some of those details will not be understood by any but men of exact knowledge with regard to dietetics and the nutritive value and chemistry of food-stuffs. If no evidence is sought upon such matters by the Royal Commission it will be tendered by witnesses none the less, because they will find it germane to the larger subjects: and its value will not be appraised. The Commission is provided, in the person of Dr. ERSKINE HOLLAND, with a professor of international law to speak as to the possible neutrality of food-carrying vessels; it is provided with an expert in banking to advise about violent fluctuations of prices; a practical farmer and a labour member of Parliament both are present, but there is neither medical man nor chemist. We think that it should not be too late to remedy the omission. An easy way to transport an ox would be in a tea-cup. An admiral can say how to guard the tea-cup, a banker can price it, and Lloyd's can insure it, but only a scientific man can say whether the substance in the tea-cup, claiming to be an ox, has the nutritive values of an ox.

Annotations.

"Ne quid nimis."

RITUAL CIRCUMCISION.

THE practice of ritual circumcision is too firmly established among the Jews to be done away with, even if that were desirable, but since the practice exists the operation should be carried out with the care and precautions of modern surgery. It is, however, frequently performed so unscientifically and so carelessly that the number of cases in which harmful results ensue is by no means small. It is true that these serious complications are most frequently seen in foreign countries, but of recent years East London and other parts of England have been so overrun with swarms of low-class foreign Jews that, as we might expect, we are meeting with similar results in this country. The chief dangers resulting from the operation of circumcision are hæmorrhage, sepsis, syphilis, and tuberculosis. Hæmorrhage is fairly readily controlled by pressure and should never prove fatal, except perhaps in cases of hæmophilia. Many instances have been recorded of fatal hæmorrhage occurring after circumcision in families of "bleeders," even though the umbilical cord has separated without any loss of blood. In one family four deaths occurred from this cause. In all these cases the tendency was inherited, as is usual in hæmophilia, through the mothers. In hæmophilic families it would be well to omit the performance of this rite. Sepsis is another important complication of ill-performed circumcision, but it is readily avoided by ordinary surgical methods. Fatal cases from sloughing and ulceration have been described. The other chief complications of circumcision are syphilis and tuberculosis and the inoculation of these diseases is chiefly due to an unpleasant method sometimes employed for stopping hæmorrhage. The bleeding surface is taken into the mouth of the operator and sucking tends to arrest the bleeding. The practice, perhaps, dates from the time when sucking any bleeding wound was looked upon as a suitable method of hæmostasis, for it is said to be no part of the rite as originally performed. However this may be the practice is in many respects highly objectionable. Even if we put aside as irrelevant in this connexion the æsthetics of the method, yet the dangers are by no means small In numerous instances syphilis and tuberculosis have been inoculated. The proofs are beyond cavil. The syphilitic manifestations have appeared in a group of children all circumcised by the same operator. There have been evidences of the primary sore and, chief proof of all, these children have in most cases affected their mothers who suckled them. There is equally certain evidence of the transference of tuberculosis. For instance, an epidemic of tuberculous disease of the inguinal glands has been found to occur in children circumcised by a rabbi affected with a tuberculous ulcer of the tongue. In one case in which the wound was not sucked syphilitic infection occurred from the operator whose mouth was affected ejecting wine from his mouth over the wound. It will be said that the practice of sucking the bleeding surface has been practically abandoned in this country. This is certainly true of the operation as performed amongst the better-class Jews, but the immigrating alien is generally less advanced and the practice still continues. Our attention has been drawn to the present state of ritual circumcision by a letter from Mr. M. Russell-Rubens who is the secretary of a society called the "Covenant of Abraham (Circumcision) Society," the object of which is to advocate that all circumcisions should be performed by a qualified medical man or under his immediate supervision, and the society hopes "to apply to Parliament to pass an Act safeguarding the lives and health of infants from the evil consequences of circumcision." Mr. Russell-Rubens points out that at present there is a large number of Russian and Polish Jews in London who were barbers or sweepers in their own country but who have taken to circumcision as a means of livelihood "with no qualification but extreme ignorance and filth." These Mohelim (circumcisors) dub themselves "Reverend" and proceed to practise without the authority of the Chief Rabbi who is supposed to appoint all operators. A discussion has recently been going on in the columns of the *Jewish World* as to the merits or demerits of these Mohelim and some of the latter have endeavoured to support their claims by asserting that qualified medical men have invited them to perform circumcision upon their Gentile patients, both adults and children. We have no means of verifying such an extraordinary claim but we have very positive evidence that one medical man at least does countenance them, for in the advertisement columns of the *Jewish World* we find an advertisement which contains a "testimonial" in favour of seven members of the London Mohelim Association. It is signed by a medical man who appends his qualifications "L.R.C.P.S. and L.F.P.S.G." It states that he has seen these seven members perform the operation of circumcision and that he has much pleasure in testifying to the ability displayed by each of them. Of course, it is possible that the advertisement was inserted without this gentleman's knowledge but that would not excuse the giving of such a certificate. Another advertisement in the same journal states that "surgical cases" are "attended to in Gentile families." We have said enough to show that circumcision as now practised is often performed in a careless manner, that there are many serious complications which may occur, leading to severe disease or even a fatal result, and that many of those who perform this rite are utterly unfitted by training for such a duty. We maintain that, since circumcision is an operation, it should always be performed by a duly qualified surgeon, or at least under his direct supervision. In no other way is it possible to have all the benefits of modern surgical practice.

DISHES FOR INVALIDS IN HOTELS.

HOTEL life is becoming much more common in London than it was 20 or 30 years ago. Whether the increased comforts to be obtained at hotels are the cause or the effect of this is a difficult question to answer, but there is no doubt that hotel managers are much more attentive than they were formerly to the comfort of their clients. We have recently received from Claridge's Hotel a little invalid menu and book of recipes for dishes suitable for invalids drawn up by Mary Nugent. These dishes are in use, not only at Claridge's Hotel, but also at the Savoy and the Berkeley Hotels. We think that this is a decidedly good move on the part of the hotel authorities, for the ordinary hotel menu is not suitable for an invalid requiring a light diet. The menu comprises broths, vegetable *purées* and soups, either *maigre* or with a veal or chicken stock, light dishes, such as soufflés, simple puddings, and such things as real calf's-foot jelly, lemonade, plasmon tea, and various cereal preparations. The recipes are simple and very good, but the last one is singularly cryptic: "Heat the teapot with boiling water, put in tea, then put one dessert-spoonful of plasmon on the dry tea-leaves; pour on boiling water (while boiling). The water must not have boiled previously."

We suppose that this last sentence means that the water must not have been boiling for any length of time previously, but there is certainly an Alice in Wonderland flavour about the paragraph as it stands. With this reservation, however, both the recipes and the system which gave them birth are to be highly commended. We may add that those persons, and there are many, who dislike "milky puddings" will find that freshly made bread sauce, eaten either hot or cold, is a most palatable substitute.

THE PARENT AND VACCINATION.

A CURIOUS dispute between a public vaccinator and the parents of a vaccinated child has recently been terminated by a special meeting of the board of guardians of the locality. The facts proved were as follows. One of the public vaccinators at Derby was informed that three children had been found suffering from small-pox in a street in that town. He went at once to the house and was told by the mother whom we will call Mrs. S., that a neighbour, Mrs. F., had been to the house on the previous evening and had also called that morning and had then inquired if Mrs. S. was going to be vaccinated. The public vaccinator proceeded to Mrs. F.'s address, meeting on the way the sanitary inspector, who accompanied him. Mrs. F. said to the inspector, in answer to a question as to what she was going to do about vaccination, "You know what my husband said last night." To this the inspector replied, "Yes, he was undecided"; and the medical man made the observation, "Well, you are running a great risk, you know. You had better be vaccinated." He then vaccinated Mrs. F. and her two-year-old child who he afterwards learnt had been in contact with Mrs. S.'s children, actually eating from the same plate as the infected children. Mrs. F.'s husband upon his return seems to have been extremely angry with his wife for permitting his child to be vaccinated and with the public vaccinator for performing the operation. The complaints which he made appear to have found support among the local anti-vaccinationists and had as their result the inquiry to which we have referred. It was alleged that Mr. F. had told the inspector that he refused to have his child vaccinated; that the public vaccinator knew of his objection; and was further informed of it by the wife who asked him to wait until her husband came home for his dinner; that he refused to do this; and further that he coerced and frightened her into consenting to her child being vaccinated by saying that she ran the risk of a fine as well as of small-pox. This story was distinctly inconsistent with the account given by the public vaccinator of what took place, and although his narrative was obviously the more probable version and his word was no doubt sufficient to convince many of his hearers, he was at the same time fortunate in having had with him a third person who was able emphatically to corroborate him in every particular. At the conclusion of the inquiry a resolution was carried by 31 votes to 1:—

> That in the opinion of this board the public vaccinator did not exceed his duty, that he is entirely exonerated from blame, and we consider that the charge against him is not proved.

In commenting upon the story which we have recounted the *Derby Express* sums the matter up by saying: "The incident throws an unpleasant light upon the difficulties which medical men have to fight in order to preserve the community from the scourge of small-pox," an expression of opinion in a lay newspaper which we cordially indorse. Before, however, the inquiry into the actual facts of the case before them was held an interesting discussion took place among the Derby guardians as to the duties of a public vaccinator in a case where to his knowledge a father objects to the vaccination of a child and the mother desires it. This question appears to have been raised on a previous occasion at a Local Government Board inquiry at Derby and a dictum of the president of that inquiry was quoted to the effect that no medical officer should vaccinate a child when the father objected "unless the mother gave him permission in writing." The Vaccination Acts speak always of "the parent," without specifying father or mother, and we observe that at the Local Government Board inquiry referred to it was also said that "the 'parent' is the father of the child when the father is alive." This is certainly in conformity with the usual view, *assuming that* the father has the child in his custody and control. In cases, however, where the mother summons the public vaccinator to vaccinate her child, or produces the child for him to vaccinate, he can hardly be expected to inquire whether she has her husband's authority to do so or not, nor should he be exposed to blame if, in such circumstances, he infers that he has "the parent's" sanction for his act. Let us, on the other hand, imagine a case in which the father has distinctly informed the public vaccinator, or any other medical man, that he absolutely refuses to sanction the vaccination of his child, and the mother, without any deception or concealment, asks the practitioner in question to vaccinate her offspring although her husband disapproves. In such a case as this we should say that the medical man, whether public official or not, would be well advised if he declined. We are not aware of any case having occurred which would illustrate what the ultimate consequences of his act might be, but the incident which we have described at Derby shows to some extent the kind of worry and annoyance to which he would undoubtedly be subjected.

PRESCRIBING IN THE LAY PRESS.

WE have frequently had occasion to comment severely on the baneful practice existing very widely in a certain class of newspaper of prescribing for such of their readers as are sufficiently credulous or ignorant to confide themselves to the therapeutic skill of the editorial staff. In such cases the diagnosis itself cannot but be doubtful, for it depends entirely on the patient's description of his symptoms, and the prescription can only be "a bow drawn at a venture." There is yet, however, a greater danger, the prescription is peculiarly liable to printers' errors and a very slight change in the dose prescribed may obviously have very important results. Of recent years there have appeared many penny weekly papers especially intended for ladies and nearly every one of these has a page in which advice is given on the mysteries of cosmetics. Much of the counsel offered is useless, even if harmless, but unfortunately the writers of these articles do not confine themselves to prescribing simple substances, but treat of the most dangerous drugs in an offhand manner which can only be accounted for by ignorance of their dangerous properties. A very typical example has recently come to our notice. There is a weekly paper called *Forget-me-Not*, intended for the perusal of girls, and a page is devoted to "boudoir gossip," where prescriptions for lotions and ointments are freely given. On this page in the issue of April 18th we find two flagrant instances of careless newspaper prescribing. In the one case a correspondent requires "a cure for pimples" on the forehead. She is told to "make up the following lotion and use frequently: One drachm of hydrocyanic acid, three drachms of glycerine; add enough water to make half a pint." There is not a word of warning as to the poisonous nature of hydrocyanic acid and nothing is said as to care in the custody of this lotion. It is by no means improbable that the patient, finding the "pimples" did not disappear, would augment the strength of the lotion in order to obtain a better result, *until* poisoning might be produced. Of course it will be said that in such a weak lotion as prescribed the hydrocyanic acid would be almost harmless, but even if this were so such a lotion should not be prescribed in lay papers. It might be thought that it would be impossible for the patient to obtain for herself the ingredients of this prescription but we fear this is not so. In spite of the Act poisons as virulent appear to be readily obtainable by the public. On the same page is given a prescription which can only be described as dreadful. A "Despairing One" asks, "Is there any remedy for enlarged pores?" and she is told *inter alia* to "make up the following ointment and apply to your face every night: one drachm of ointment of zinc, one ounce of nitrate of mercury, and four drops of creosote." The only pharmacopœial preparation to which the name nitrate of mercury can be applied is the liquor hydrargyri nitratis acidus, a most caustic application, so that if the prescription were dispensed as written a violent escharotic would be applied, with results horrible to contemplate. The paper would seem to be well named *Forget-me-Not*, for no one who essayed this treatment would ever forget the source whence it proceeded. Possibly the writer intended to advise one of the ointments of nitrate of mercury, but the prescription gives no hint to this effect and we cannot but take it that the risk of the prescription being used as written is very great. No pharmacist would dispense it as it stands, but there is always a chance that the recipient of this advice may prepare the application herself. Lifelong scars might be the result. It is from no feeling of professional jealousy that we draw attention to these unpardonable mistakes but from a conviction that all such uneducated and haphazard prescribing, even for cosmetic purposes, can rarely succeed in benefiting those who take the advice and may result in irremediable damage or may even lead to a fatal issue. We have referred particularly to one publication but it must not be imagined that the paper mentioned is necessarily a greater sinner in this respect than its contemporaries; they all err in venturing to undertake functions for which they are not fitted and we earnestly advise them to reconsider their position.

OPERATIVE TREATMENT OF FRACTURED PATELLA.

WIRING a fractured patella was suggested by Severini and seems to have been first practised in America by Rhea Barton, and a little later in this country by Cooper, but the results were unfavourable, *two out of five patients dying*; these results naturally led to the abandonment of the operation. After the introduction of antiseptic surgery wiring the patella was performed by Cameron of Glasgow and the operation has attained a wide popularity. The methods of wiring employed are numerous. Most commonly a single wire unites the broken edges but does not invade the posterior surface of the bone. Mr. A. E Barker has employed a method in which the wire passes vertically all round the bone, one portion lying between the patella and the femur and the other in front of the patella Circumferential wiring has also been done, and in this form the wire passes round the margin of the bone, piercing the tendon of the quadriceps above and the ligamentum patellæ below. All these methods give good results and the individual predilections of the surgeon usually determine the form which he adopts. In THE LANCET of April 18th, p. 1101, we published an account of wiring a fractured patella by Mr. B. C. Stevens of Mexborough, who urges that to obtain the best results two wire stitches should be employed, chiefly in order that passive movements of the knee-joint may be commenced early and thus stiffness avoided, but also because the two stitches hold the fragments together much more firmly than does a single wire. *There is much to be said in favour of the* double wiring and many surgeons employ it habitually, for a single wire has been known to give way, but the results of all the methods of wiring are excellent if asepsis be maintained.

MEDICO-LEGAL ASPECTS OF DEATHS UNDER CHLOROFORM.

AN action involving important issues has recently been decided in a Scotch court of session before a judge and jury. The facts as stated by the claimant were briefly as follows: Andrew Gillies, the claimant's late husband, suffered from some injury to his arm as a result of which adhesions had formed. He decided, after consultation with his own medical adviser, Dr. John Cunningham of Stewarton, to have an operation performed to remedy this. The widow further stated that although the deceased had taken a hearty meal—his tea—and in spite of his expressed reluctance, he was without any adequate preparation taken by Dr. Cunningham into a room and given chloroform. The man was placed on a couch and told to inhale the drug from a folded towel held by the medical man. He counted aloud to 30; the operation was performed and simultaneously Andrew Gillies appeared to have died from syncope. The only other persons in the room were the son of the deceased and another youth. In spite of artificial respiration consciousness never returned, nor indeed was there any appearance of revival. Upon the opposite side the evidence of Dr. Cunningham and Dr. J. C. Taylor, who was summoned when artificial respiration failed to resuscitate the man, was that Dr. Cunningham operated at the time he did at the express desire of the deceased and that he was under the impression that all necessary precautions as to diet, purgation, and so on, had been duly taken. As the learned judge in his charge to the jury said, the evidence upon certain plain matters of fact was absolutely divergent. The jury found for the defendant, Dr. Cunningham, so that Mrs. Gillies's plea for £1000 damages failed. The difficulties and exigencies of country practice add greatly to the anxieties incurred when an anæsthetic has to be administered, since from their very nature many precautions, and in many cases assistance, have to be dispensed with. When, however, it is realised that any practitioner may be called upon to face such charges as the one Dr. Cunningham had to meet too much care cannot be taken or too much importance attached to the use of so powerful a drug as chloroform. It was urged at the trial that the *deceased refused* to incur the expense of the services of a second medical man as "the operation was so slight." But surely any reasonable person can be made to understand that however trivial may be an operation the inhalation of chloroform involves the same risks whatever may be the surgeon's work. In self defence no medical man should consent to risk *his patient's life and his own* professional reputation by undertaking both to give chloroform and to operate. In view of the gravity of the issues involved medical men will in every case be well advised if, besides explaining what preparations are necessary before chloroform is inhaled, they will actually see that their instructions are carried into effect. We do not, of course, call in question any accepted method by which chloroform is given, but we may perhaps urge that at the present time, when *chloroform* is known to be dangerous in proportion to its concentration, the most precise methods should replace those which permit of the use of unmeasured doses. We congratulate Dr. Cunningham upon the only issue of the case which the circumstances warranted. But the evidence in this case possesses points of further interest. Several experts were called—Scotchmen presumably versed in the teaching of Syme and his following—and their *obiter dicta* are at once interesting and instructive Professor Carstairs C. Douglas (Glasgow) is reported to have estimated the mortality from chloroform as 1 in 2000, although he regards such fatalities as "uncommon occurrences." He stated that the essential cause of death was "syncope" and not asphyxia. Professor J. Glaister of Glasgow, speaking of his experience, stated that he had performed 30 examinations of bodies of persons who had died under chloroform within the last five years. In his view also death arose from cardiac syncope. This conclusion was the same as that at which Dr. Joseph Bell of Edinburgh arrived and in cross-examination Dr. Bell is further reported to have said that the too rapid administration of undiluted chloroform acted as a poison to the circulation and caused "syncope" and sudden death. Professor H. Galt of Glasgow was even more emphatic. In 13 post-mortem examinations which he had made on persons dying under chloroform he found every one had died from cardiac "syncope." We thus have admitted 43 necropsies upon persons dying under chloroform within one district of Scotland—a fact which appears almost to justify the assumption that even the methods employed north of the Tweed cannot be relied upon to avert what we have always impressed upon our readers is a danger whenever chloroform is used and whatever is the method pursued. It is matter of history, although history like other branches of learning is at times neglected in controversies, that Simpson believed and taught that chloroform killed in certain cases by causing circulatory paralysis, or, as he put it, by syncope. It is, however, not always recognised in London that the authorities on toxicology in Scotland accept Simpson's and reject Syme's teaching upon this important point. In conclusion we must draw attention to a portion of the admirable charge of the Lord Justice Clerk. In substance he said that the law in such cases was that a person was not liable in the exercise of his profession for a mere mistake or mere failure in some detail which might cause injury to another. To establish a claim there must be what in Scotland is called gross negligence, in England crass negligence. This is a clear statement of what is a matter of supreme importance to medical men. In the present state of our knowledge and in view of the imperfection of our anæsthetic appliances it cannot be too clearly put that a fatality under an anæsthetic need not, and we hope never is, the direct result of the carelessness or incompetence of the administrator and therefore does not place him in danger of being mulcted in damages for a calamity as terrible to him as to all others concerned. There is one more point. Much stress was laid in the claimant's pleading that the medical man had not in his possession at the time of the accident strychnine or ether to be used in emergency. It is certainly well worthy the consideration of all practitioners who undertake the duties of an anæsthetist that they should never be unprovided with such instruments and drugs as may in an emergency be required and which in some cases may turn the scale in the patient's favour.

MUNICIPAL INFANT MILK DEPÔTS.

THERE is no doubt that if the excellent system of providing municipal depôts for the supply of wholesome milk and milk of standard composition for the use of babies were universally adopted infant mortality would be enormously reduced. The experience of such places as St. Helens, Liverpool, and Ashton-under-Lyne, where such an experiment has been made, affords pretty conclusive evidence in favour of this view. A similar undertaking was begun in 1901 by the Battersea borough council and we have recently received a copy of an interesting report of the medical officer of health, Dr. G. F. McCleary, dealing with the working of this infants' milk depôt since its opening on June 5th, 1902, to the end of the year. The method adopted is that initiated by Dr. Léon Dufour at the Goutte de Lait, Fécamp, and consists in supplying sterilised cow's milk brought as near as possible to the composition of human milk in stoppered bottles, each bottle containing sufficient food for one meal and no more. The number of children being fed with this milk at the present time is about 360. Dr. McCleary puts forward evidence of two kinds that the Battersea depôt has justified its existence. Firstly, there is the testimony of medical practitioners who have had practical experience of the effect of the milk and, secondly, there is the evidence of statistics, though, as he adds, it is doubtful whether the full value of the work of the depôt can be expressed in figures. Taking all things into consideration, however, there can remain very little doubt of the influence for good gained by the adoption of the scheme. Thus from one table it would appear that the mortality of infants in the borough during the last six months of 1902 was 87·5 per cent. higher than the mortality in the depôt-fed children, whilst taking the mortality in east and north-west Battersea only the difference is no less than 103 per cent. We congratulate the borough council on taking this excellent step, showing as it does results of the highest hygienic importance and it is to be hoped that other municipal authorities will follow such a good example.

GREY'S HOSPITAL, PIETERMARITZBURG.

WE have received a pamphlet of 46 pages containing newspaper comments and correspondence with reference to the movement for the reorganisation of Grey's Hospital, Pietermaritzburg, which movement was commenced by the Pietermaritzburg Medical Society at a meeting held on August 12th, 1895. This society then passed a resolution in favour of allowing medical men to attend such of their patients in Grey's Hospital as desired their services instead of its being compulsory on such patients to accept the medical superintendent of the hospital as their medical attendant. This resolution was sent to the board of trustees for the control and management of Grey's Hospital, but the board's reply, which was received on Dec. 6th, 1895, was unfavourable. On August 4th, 1896, the society again communicated with the board, recommending (1) the promotion of the medical superintendent to the status of honorary consulting physician and surgeon and the appointment by the board of four or more additional honorary physicians and surgeons; (2) that the board of trustees should apply to the general public for additional funds for the hospital; and (3) that private paying patients might at their own cost have their own private medical men to attend them at the hospital, and also that nurses should be trained for attendance on patients at their own homes. This recommendation was referred to the Colonial Secretary in Natal who, on March 11th, 1898, replied stating that the proposed arrangement was not desirable under the present system of management of Grey's Hospital and that the Government saw no sufficient reason for any further representation to the board of trustees on the subject. On May 14th, 1901, the society (which had by that time assumed its present name of the Pietermaritzburg Branch of the South African Medical Association) petitioned the Governor of Natal making a variety of suggestions for the reorganisation of the hospital, some of them being that visiting physicians and surgeons should be appointed, that their term of office should be five years, that those patients who can pay ordinary medical fees should be in a separate ward and should have the privilege of being attended by their private medical man, that the training of nurses should be undertaken, and that the medical staff should be allowed to select two of their number to sit on the board of management. On Sept. 10th, 1902, a meeting, presided over by Mr. S. J. Mason, mayor of Pietermaritzburg, was held, at which a resolution was adopted embodying various recommendations, two of them being to the effect that the public should be invited to subscribe to the funds of the hospital, and that a complete scheme should be drawn up either for a new hospital or for enlarging the present one. A building fund was at the same time established and on Nov. 3rd a conference was held between the hospital board and a deputation from the building fund. The deputation inquired whether the hospital board would be willing to receive the assistance and coöperation of the executive committee of the building fund in the matter of providing a new hospital and whether the board would agree to its constitution being so altered as to admit of representatives of subscribers to the building fund having a voice in the management of the hospital. The board in reply passed a resolution as follows :—

> The board welcomes the coöperation and assistance of your committee but regret that they cannot accede to the request for the [illegible]

It may here be explained that the board which at present manages the hospital is elected partly by the town council and partly by Government, the Government contribution in aid of the expenses being £5000 a year. The local press speaks strongly in favour of the proposed reforms and reorganisation which are naturally supported by the medical men of the district. The medical members of the executive committee of the building fund are Dr. D. Campbell Watt, Dr. O. J. Currie, and Dr. W. Russell Strapp. Commenting on the present position of the controversy the *Natal Witness* of March 6th says: "We believe the desire and the intention of the Government is to place the hospital completely in the hands of one man who shall be directly responsible to them and to make of it yet another hide-bound Government institution in regard to which the public voice will stand for naught. ...... Under the scheme which the Government and the present dutiful board have in mind local practitioners will be precluded from visiting the hospital, which would be conducted on even narrower lines than hitherto."

THE PREVALENCE OF SMALL-POX.

A TELEGRAM from Barbados received at the Colonial Office on April 14th states that there has not been any further case of small-pox in Barbados since April 4th. In accordance with the provisions of the Quarantine Act clean bills of health are being issued. The Bradford and West Riding Medico-Ethical Union at a recent meeting approved of the following memorial to the President of the Local Government Board :—

> That in the opinion of your memorialists it would lead to the extension of the practice of vaccination in this country if Parliament were to enact that every duly qualified medical practitioner shall be put on the same footing in regard to the practice of vaccination as that on which public vaccinators now are. It is well known to your memorialists that many adult persons who refuse to visit the public vaccinator would have their children vaccinated and would be themselves revaccinated if this could be done free of cost to themselves by their regular medical attendant.

The Lancashire County Council has issued as a circular some admirable advice extracted from the report of the county medical officer of health dated April 16th. The portion extracted lays down the necessity of obtaining medical advice as early as possible and points out that vaccination and revaccination are the only means by which a person can defy small-pox. At the meeting of the Brantham rural district council held on April 14th a case of small-pox was reported from Barrowby. The case was that of a man who had been employed to clean a house from which a small-pox patient had been removed. The Barrowby man was an anti-vaccinationist but said that he was not afraid. However, he very soon sickened with small-pox. The Local Government Board for Scotland intimates that during the period from April 1st to 15th inclusive 3 cases of small-pox have been notified to it from the burgh of Dundee, 2 from the burgh of Leith, and 1 from the burgh of Brechin.

A MEDICAL CORONER FOR MANCHESTER.

WE understand that Dr. G. H. Darwin of West Didsbury, Manchester, is a candidate for the appointment of coroner for the city of Manchester which has been rendered vacant recently by the death of Mr. Sidney Smelt. Readers of THE LANCET know how persistently we have advocated the appointment of medical coroners—indeed, the movement to secure this office for a medical man had its origin 40 years ago in our columns. The coroner's inquest is an inquiry into the cause of death and in a very large percentage of cases the medical evidence as to this cause is the only evidence really essential to the finding of a true verdict. Surely a medical coroner can elicit such evidence from a medical witness and can instruct a jury upon its value in a manner that no layman, however skilled in the rules of evidence, can possibly do. We wish Dr. Darwin every success.

THE ASSOCIATION OF CERTIFYING FACTORY SURGEONS.

THE annual meeting and dinner of the Association of Certifying Factory Surgeons is to be held at the Hotel Cecil, London, on Friday, May 22nd. It is intended to make the dinner the occasion of a notable gathering of authorities on factory and workshop legislation and administration and it is expected that many Members of Parliament, Government officials, and persons prominent in dealing with labour questions will be among the guests. Mr. A. Akers-Douglas, the Home Secretary; Mr. Cochrane, the Parliamentary Under-Secretary; and Sir Kenelm Digby, the Permanent Under-Secretary of the same department; Sir John Batty Tuke, M.P., and Sir Charles Dilke, M.P., are among those who have already accepted invitations. In addition to the official guests many members of the association have expressed their intention to invite as private guests the Members of Parliament of their own particular districts. In this way a representative gathering should be secured.

CONTRACT PRACTICE IN THE COUNTY OF DURHAM.

A STRUGGLE which commenced just four years ago is still going on in the county of Durham, where an energetic medical union is striving to obtain an increased rate of remuneration for medical attendance on the miners and other workmen in the county. At some collieries there has been strong opposition to the increase of rates of payment to the medical men and the miners by advertising in the lay papers have been able to persuade medical men to accept appointments on the lower terms, thus ousting the previous medical men. A circular issued in March, 1899, by Dr. Edward Jepson, *President of the Durham Medical Union*, ran as follows :—

> We trust to the dignity and uprightness of our brethren in the profession that they will not take advantage of the offers made by the miners but in every way support this effort to obtain what is just.

To some extent this circular met the point, but certain medical men have, however, been found to fall in with the miners' views. A strong letter in our present issue from Dr. Jepson points *out that the position of these men cannot be recognised by* the medical union even if the miners should raise their salaries to the sum demanded by the union. They hold their posts by accepting terms which their predecessors have refused and they cannot again come health in the Catholic University Medical School, Dublin, and examiner in sanitary science in the Royal University, as delegate to attend the International Health Congress to be held at Brussels in September.

THE annual dinner of the Pharmaceutical Society of Great Britain will take place in the Whitehall Rooms of the Hôtel Métropole, London, on Tuesday, May 19th next, at 7 P.M.

THE Paris Société de Pharmacie has elected Dr. D. MacAlister of the University of Cambridge a corresponding member of the Society.

THE FOURTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

(FROM OUR SPECIAL CORRESPONDENT.)

Madrid, April 17th.

STARTING from England, Paris is naturally the first stage on the road to Madrid, and here it must be confessed the Congress news was not encouraging. First of all, the French railway companies had never so much as heard of the International Congress of the Medical Press, but were quite ready for the influx of travellers desirous to attend the Fourteenth International Congress of Medicine. A reduction of 50 per cent. has been promised on the railway fares and is granted, but no congress should ever be satisfied with such an assertion, however correct in the literal sense. It is always necessary to go into details. In this instance the details are numerous and have in some instances proved fatal, for instead of reducing they have considerably increased the expenses incurred. The reduction undoubtedly is granted, but the intending traveller must not only possess all his papers in perfect order but when he presents them at the railway station he is told that they must be countersigned by the secretary of the Orleans Railway Company, not at the railway station, but at the head offices in the centre of the town, and that this will only cover the journey from Paris to Bordeaux. For the rest, from Bordeaux to the Spanish frontier he must obtain the signature of the Midi or Southern Railway Company, which is quite a different company and its offices are in another street. Further, if the intending traveller happened to be a French medical practitioner he was informed that the railway company secretaries would not give their signatures unless his papers were signed by Dr. Brouardel who until recently was dean of the Faculty of Medicine and is going to Madrid where he will preside over the French delegation. As might well be expected, Dr. Brouardel protested vehemently. He was not a clerk that he should be called upon to sign railway passes. It was no concern of his; why should he be expected to certify to the *bona fides* of every French medical practitioner? Such a work would require time and as a result the applications that were made to him involved a delay of at least 24 hours. So many were the complaints thus occasioned that one of the railway officials suggested that it might be avoided by the French practitioners professing to come from the French-speaking provinces of Belgium. It is in consequence of this suggested stratagem that an extraordinary number of members will appear to have arrived from Mons in Belgium. However, and in spite of every effort, it took at least four days to obtain all the necessary signatures. It is true that for the modest charge of one franc an agency undertook to attend to these formalities, but many do not care to trouble an agency from which they are not obtaining hotel and other tickets, and the agency itself was complaining about the amount of unrequited work thus entailed.

Dr. Blondel, as general secretary of the International Association of the Medical Press, has been striving to facilitate matters and has suggested that a special office should be opened at the Orleans station where all the formalities could be gone through at once and on the spot and thus the delay be saved of some four days in Paris. One of the two companies had assented to this when I left Paris. If the other company also agrees then the troubles described will cease to exist. In the meanwhile I had for travelling neighbour on the way southwards from Paris a member of the Congress who had come with his wife from Poland. He entered France at the frontier between Metz and Nancy. There no one knew anything about the Congress and any reduction on the fare was refused, but he did obtain a statement that he had paid full single fare and therefore vaguely hoped that somehow or other he would be allowed to return for nothing. In Paris he was treated most politely, but it took him the full four days to obtain the necessary signatures. During this time he calculates that he spent 250 francs and that the value of the reduction in railway fares that he obtained will amount to 120 francs, so that he is distinctly a loser by the transaction. Further, having thus lost four days he is no longer able to carry out an intended trip to Andalusia before the Congress meets.

Over and above these difficulties the most alarming rumours have been in circulation as to the exorbitant prices of the hotel accommodation in Madrid. My Russian fellow traveller had sent 50 francs to Madrid so that a room might be secured for him; the receipt of the money had never been acknowledged and he had not any idea whether any efforts had been made on his behalf. On arriving in the early morning at Madrid I found the agents at the station talking glibly of 60 and 70 pesetas per day for a room, that 6000 or 8000 members of the Congress were expected, and that there were only 3000 rooms available. In Paris I had been assured that out of 400 French medical practitioners who had enrolled themselves as members of the Medical Congress and had paid their subscriptions, only 160 were really going, the others being deterred by the fear of exorbitant charges and formalities and difficulties. All these rumours have a foundation of truth. There certainly have been difficulties and loss of time incurred with the companies, though this has been obviated by the travelling agencies when employed for that purpose. On the other hand, it is some of these travelling agencies that are, I was assured, responsible for the alarming rumours concerning the prohibitive charges made at the hotels. There are some six hotels at Madrid that are known to the travelling public all over the world. They are cosmopolitan hotels, such as may be found in any large town and where the traveller who, though abroad, wants to change his immediate surroundings as little as possible, will find much the same accommodation as exists in most other parts of Europe. Some agents made a descent upon these hotels and themselves hired the greater part of their rooms. Having thus secured a monopoly and made a "corner" in rooms they ran up the price to fancy figures. At the offices of the Congress I was told that Dr. Brouardel had been asked 200 pesetas per day for a room in one of the well-known hotels. Another delegate, an Englishman I believe, is actually paying 150 pesetas per day for one large room on the second floor in another of these hotels. Had the members of the Congress been able to deal directly with the proprietors or managers of the hotels they would have had to pay more than the usual prices but nothing like such extravagant charges.

All this is the more regrettable as after all there is no difficulty whatsoever in getting rooms and at reasonable rates. The organisers of the Congress appointed a long time ago a special committee to look after this matter under the management of M. Ulrich Frei. Any number of inhabitants of Madrid have been to this committee and offered one or two rooms in their own private houses, and these, together with the hotels and boarding houses that are not known internationally, suffice for all purposes. If it were necessary sleeping accommodation could be found for 10,000 visitors, and even according to the most sanguine expectations there will not be more than about 5000 Spanish and foreign members of the Congress. At the offices on the evening of April 16th the names of 2180 foreign members, who are to be accompanied by 630 ladies, had been inscribed. But it is quite certain that many persons who have paid their subscription will at the last moment alter their minds and not come. On the other hand, there are many others who never intended to come and will join only at the latest hour. According to one of the committee men in charge of the correspondence, &c., the number of members actually present at the Congress, counting both Spanish and foreign members, will not amount to 3000. As already stated the most sanguine scarcely count on more than 5000. Therefore there should be no difficulty about securing rooms and any extortion that has been practised has been due to "rigging the market" and not to any paucity of accommodation. This is a somewhat serious matter. If the representatives of the medical profession cannot meet without giving rise to a sort of conspiracy to extort from them

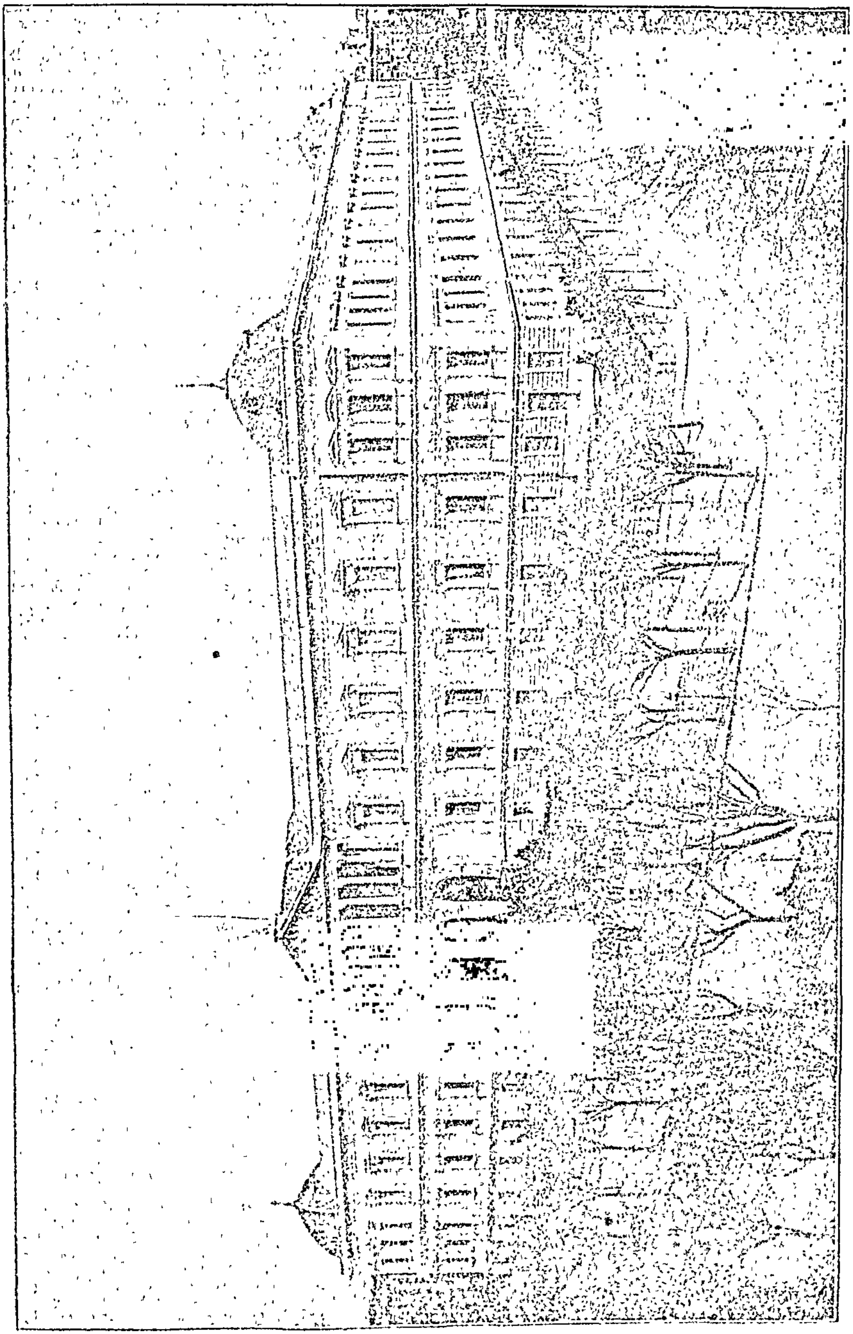

FIG. 1. The Royal Library and Museum, Madrid. The headquarters of the International Medical Congress.

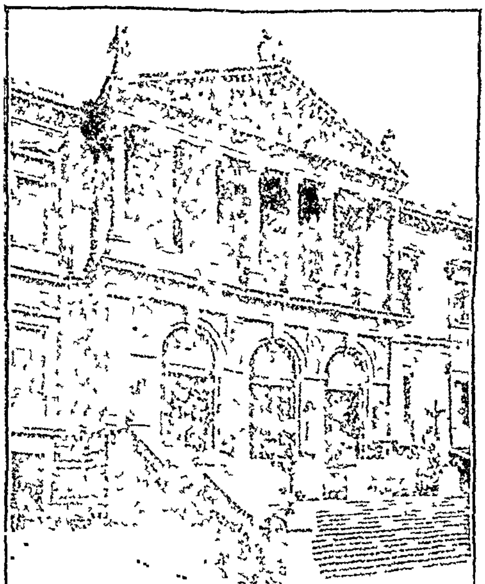
extravagant payments some measure must be taken to check such practices. Combination must be met by combination, and this to some extent is what has actually been done by the creation of the Service des Logements. I was pleased to find on arriving at Madrid that what was stated in THE LANCET on this subject in the issue of Feb. 14th (p. 456) has proved to be correct. Nor is this all. This Service will have its agents now at the railway stations to await the passengers and give them every help the moment they arrive and thus, if possible, prevent their falling into the hands of the harpies who are seeking unduly to exploit the situation. It only remains for the medical men to support the organisation formed by their fellow medical men of the reception committee and not be led into the toils of those who have sought to create a monopoly and then to practise extortion by pretending that there is no room.

Madrid, April 18th.

It has been not only a matter of difficulty to lodge satisfactorily all the members of the Congress owing to the reasons which I have just set out but it has also been very difficult to find a suitable meeting place for the Congress itself. There are 16 sections, each needing a meeting place of its own, and then there are all the offices, secretaries' rooms, &c., that likewise take up much space. Naturally the Faculty of Medicine seems an appropriate place for the holding of a medical congress. It is, however, an old building attached to a large and antiquated hospital at the far end of the Calle Atocha. This is a populous part of the town, the approaches are not of the best, and, in a word, it is not the sort of neighbourhood which the organisers of the Congress particularly cared to show to their foreign guests. Thus, while it was admitted as a sort of abstract principle that the Congress should meet at the Faculty of Medicine, yet everyone concerned was firmly determined that much better premises should be obtained. That this should be so was the more natural as a precedent had already been established in 1898, when the Ninth International Congress of Hygiene and Demography met at Madrid. Like the Ring Strasse at Vienna, so also at Madrid, there is a magnificent garden thoroughfare which constitutes the fashionable lounge and is known as the Prado. It is so broad that it holds several rows of trees, with gardens and fountains interspersed amid the junction of roads. Palaces, picture galleries, the monumental National Bank, and other splendid buildings line the sides of this, the Champs Elysées of Madrid. Among these buildings is the, comparatively speaking, new Palacio de la Biblioteca y Museos Nacionales. This enormous building was commenced in 1866 and concluded in 1894 On the ground floor there are the natural history and the archeological museums, while on the first floor there are a great number of palatial rooms containing the museum of modern painting and art. It was in these rooms and surrounded by splendid pictures that in 1898 the various sections of the Congress of Hygiene and Demography met. But there is also within this vast building the national library, containing some 30,000 very rare and valuable MSS. and more than 500,000 printed volumes. Here it is that the hitch in the arrangements has arisen. The chief librarian, as one of his enthusiastic admirers explained to me, is one of those remarkable men who may be seen perhaps once in 200 years. His knowledge of books is so extensive and minute that it can only be looked upon as marvellous. It seems as if he could not forget anything he has ever read and he will frequently also remember the page and the line where any particular passage occurs. To have secured the services of such a scholar as chief librarian is naturally most fortunate and all Spanish students are proud of their celebrated librarian Now this explains the difficulty in which the organisers of the Medical Congress found themselves. They wanted the Congress to meet at the museum ; but the librarian replied that the museum was in no wise connected with medical science, that students came from all parts of the world to study in the library under his charge, and that it was not right to disturb them. The objections that any other librarian might have made would probably have been set aside with but little scruple or hesitation, but in this case the great admiration and respect felt for so remarkable a person as the present librarian made the authorities hesitate and postpone the unpleasant task. At last, however, the librarian was sent for by the Government and given to understand that this was a question of international politics, that the premises belonged to the nation, and that the nation was anxious to give its foreign guests the best possible reception. So the librarian had reluctantly to consent to the closing of the library for a few days.

But now another obstacle had arisen. The museum, it will be seen, is a huge building, simple in character, with the exception that there are a projecting monumental entrance and central façade. (See Fig. 1.) Here are a flight of steps leading up to three splendid art ironwork doors. On the floor above are a colonnade and balcony and over this are some splendid sculptures. When the building of the museum was completed the sculptures were but partly done. The sculptor had much to do, the statues were being carved at Carrara in Italy, and there was no knowing when they would be completed. Therefore and so as not to spoil the general effect of the building, and, indeed, so as to be the better able to judge what this effect would be, plaster models of the proposed sculptures were put up and there they have been for some years. A few months ago, however, the statues were at last completed. They arrived at Madrid and were given up to the authorities. Of course the thought naturally arose that it would be well if the plaster models could be removed and the real sculptures put up before the Congress assembled. Señor Sagasta was then Prime Minister and a well-known architect, Señor Mariano Belmas, was asked if this could be done in time for the Congress. Though it would be necessary to erect very solid and elaborate scaffolding so as to take heavy statuary up to the height of the roof safely, still Señor Belmas undertook to do it all in time. The work was begun but shortly afterwards, as all the world knows, Spain lost one of her greatest statesmen—Señor Sagasta died. The Liberal party, deprived of his able leadership, collapsed and the Conservatives came into power. But Señor Belmas is not only an architect, he is also a Senator and was wont to vote on the Liberal side. Now it somehow happened that some difference arose between him and the sculptor. The Conservative Government thereupon informed Señor Belmas that he need not trouble about the matter any more as they would appoint some other architect to finish the work. All this concerns the Medical Congress because this policy of "changing horses while crossing the stream" has occasioned such delay that the scaffolding is still there, and it is doubtful whether it will be possible to get it all down before the Congress is over In the meanwhile the members of the Congress will have to enter the museum by some back doors instead of ascending the majestic flight of steps and passing under the art sculptures which have now just been hoisted into their places but are still hidden by the

FIG 2



Entrance to the Museum, showing plaster statuary.

surrounding scaffolding. This miscalculation and delay are characteristic, a little *cosa España* of itself.

FIG. 3.

Entrance as it is, with scaffolding erected before it.

Other more serious delays have also happened. The members of the Congress will not mind much by which door they enter, but many complaints have been made because the various reports which were to serve as the basis of discussion in the different sections have not been sent out. Theoretically, these reports should be circulated among the members of the sections whom they concern some six weeks before the Congress meets and they can then be studied and the members can prepare their criticisms. Thus carefully thought out arguments could be brought forward during the discussions at the meetings of the sections. This, however, has not been done. The reports are not printed and there is no likelihood of their being published till long after the Congress ends. This, however, is not the fault of the organisers of the Congress. The reporters who were appointed have, for the most part, delayed and postponed *doing the work, and finally nearly all the reports came in* together at the eleventh hour. It was simply useless to attempt to do anything with them. *Madrid is not a town* like Paris or London. In Paris there are a good many English compositors, and in London there is no lack of type-setters who can set up French manuscripts. This is not so in Madrid. Therefore the proofs have to be corrected and re-corrected over and over again. There is a circular now in hand which has taken more than two months to print and my informant had only just corrected what he hoped would be the last revise. Thus even to-day the definitive programme of the Congress is not yet printed and it will be fortunate if it is ready a few hours before the Congress begins. This is not altogether the fault of the organisers of the Congress, for the facilities that exist in great commercial centres such as Paris and London cannot be expected in a small and purely political town like Madrid *On the other hand, the members of the reception committee* are very much alert and are with never-failing courtesy ever ready to help and to advise the new arrivals.

Madrid, April 19th.

It is not one Congress but a whole series of Medical Congresses that is about to be held. This series will begin at 3 o'clock to-morrow afternoon, April 20th, when the *Minister of Public Instruction will open the International* Congress of the Medical Press. This Congress will meet at the Madrid University, and though it is said that no less than 100 Spaniards who claim to be connected with medical periodicals will be present the attendance from other countries will be small. This is due to some extent to the alarm caused by the rumours prevailing concerning the exorbitant charges made for rooms in Madrid, a question which I have already fully explained. In the evening the President of the Congress, Dr. Carlos M. Cortezo, will receive the delegates at his own house, and it is only on the Tuesday morning that the Congress will really get to work, when the general secretary, Dr. Angel de Larra, will read the correspondence and report on the general situation. In the afternoon of Tuesday there will be a further business sitting and in the evening the representatives of the medical press are to be received and entertained by the General Association of the Political and Literary Press. On Wednesday morning all business must be concluded, for there is to be a midday banquet, followed by the formal closing of the Congress, and then a reception at the town-hall and some representation at a theatre. As yet I only know of delegates coming from Belgium, France, Italy, Germany, Norway, and Great Britain.

Then on the Thursday the great International Congress of Medicine will begin, or rather the opening ceremony will be held in the Theatre Royal. The stage will serve as the platform where the King, the Queen Mother, the Ministers, and the principal personages of the Congress will be seated. The members of the Congress will occupy the floor of the great building, while in the boxes and galleries ladies and friends will be able to obtain a good view of all the proceedings. Many of the projected receptions and entertainments have already been announced. *Their Majesties* will throw open the palace to the congressists and there is also to be a Royal garden party. The Government and the municipality are likewise preparing entertainments for the members of the Medical Congress. But the definitive programme has not yet been published; indeed, the last details will only be settled to-day—that is to say, only four days before the Congress actually meets. *It will conclude on April 30th, but on* the very next day another Congress will commence. This is a congress of Spanish-speaking European and American medical men. The Spanish-American Congress, as it is briefly called, will only sit for two days. Finally, on May 3rd the fourth and last Medical Congress will meet. This is a purely Spanish national Medical Congress which is convoked to discuss questions of medical deontology or ethics. But somewhere amid these four Congresses there is to be a meeting of medical men and other persons who in some official capacity are concerned in the preservation of public health. The Deontological Congress will close on May 5th. Thus a whole fortnight is to be devoted to these four Medical Congresses. The population of Madrid will never before have heard so much about medical men and their concerns The daily papers are already publishing columns of personal details concerning the leading members of the forthcoming congresses, and yet in the midst of it all there is to be a general election and there are ugly rumours concerning hunger riots in the south of Spain It is perhaps not the least of the many *compliments medical science is* [illegible] during the course of the next few days. [illegible] and to make the members thoroughly welcome.

FOOD IN WAR TIME: A ROYAL COMMISSION APPOINTED.

THE King has been pleased to appoint a Royal Commission to inquire into the conditions affecting the importation of food and raw material into the United Kingdom in time of war. The reference to the Commission is "to inquire into the *conditions affecting the importation of food* and raw material into the United Kingdom in time of war and into the amount of the reserves of such supplies existing in the country at any given period and to advise whether it is desirable to adopt any measures, in addition to the maintenance of a strong fleet, by which such supplies can be better secured and violent fluctuations of price avoided." The following are the names of the Royal Commissioners:—H R H. the Prince of Wales; Lord Balfour of Burleigh (Chairman), Secretary for Scotland; the Duke of Sutherland; Lord Burghclere, formerly Minister of Agriculture; the Right Hon. Henry Chaplin, M P., formerly Minister of Agriculture; the Right Hon. J. L. Wharton, M.P., a director of the North-Eastern Railway; Vice-Admiral Sir Gerard H. C. Noel, who has commanded the Mediterranean Fleet and was a Lord of the Admiralty from 1893 to 1898; Sir John Colomb, M.P.; Sir Alfred Bateman, K.C.M.G., Comptroller-General of the Commercial, Labour, and Statistical Department of the Board of Trade; Sir H. Seton-Karr, M.P.; Mr. Henry H. Cunynghame, C.B., Assistant Under-Secretary of State, Home Office; Mr. E. Robertson, M.P., a Civil Lord of the Admiralty from 1892 to 1895; Mr. A. Emmott, M.P.; Mr. John Wilson, M.P.; Professor Erskine Holland, D.C.L., Professor of International Law, Oxford University; Mr. A. S. Harvey, of Messrs. Glyn, Mills, Currie, and Co., the bankers; Mr. J. E. Street, the chairman of Lloyd's; and Lieutenant-Colonel R. Montgomery, President of the Liverpool Corn Trade Association. Mr. W. H. Clark, of the Board of Trade, will act as secretary to the Commission.

MEDICINE AND THE LAW.

The Risks of Medical Practice.

THERE is a class of criminal charge which beyond all others is easy to make and difficult, or in many cases impossible, to disprove—we refer to charges involving unlawful carnal knowledge of females or indecent assault upon them. Accusations of this kind have also the peculiar feature that more than others they are liable to be made without any foundation whatever, either maliciously or because the disordered fancy of a woman or girl believes them to be true. Baseless charges such as these are by no means rare. They may be brought against men of any rank or calling, but, unfortunately for themselves, medical practitioners are more exposed to them than all others owing to circumstances incidental to the practice of their profession which are too obvious to require detailed explanation. With medical practitioners may be included dentists, not because they are called upon to make examinations or to perform operations likely to suggest the subject matter of a criminal charge, but because they are daily brought in contact with women of whose idiosyncrasies, mental and physical, they know nothing, and in their interviews with whom they are less likely than are medical practitioners to avail themselves of the presence of a third person. In THE LANCET of Jan. 31st, 1903, p. 344, it was suggested that if charges of indecency are to be sustained in courts of law without any direct corroboration of material particulars being insisted upon it will not be safe for a medical man to see patients alone. As a matter of practice evidence to some extent bearing out that of the prosecutrix is expected to be given in all cases of the class under consideration and in some it is specifically required by statute, but it is as well to point out that much of the corroborative evidence which is accepted as such at trials of this kind can hardly be said to bear directly or in any way conclusively upon the accusation made. Such testimony when there are no eye-witnesses and when there is nothing to prove that an alleged struggle took place usually includes the fact that the prosecutrix made a complaint to someone and stress is laid upon the question whether the complaint was made as soon as possible after the time of the supposed act. It is, however, by no means unlikely that the person making a complaint of an assault which never took place should make it immediately after the interview or meeting which may have suggested it to her mind and which in any case will lend colour to the accusation. Another class of corroborative evidence is that which medical men themselves are required to give. It, as a rule, consists in their being asked to make an examination of the sexual organs of a woman or girl and then to depose in the witness-box to conditions observed in them and bearing upon the charge made. In some cases extreme violence is alleged by the prosecutrix and the evidence of the medical man may negative this. In others it may tend to confirm the story she has told, but at the same time the presence of bruises or laceration does not necessarily prove that the accused person was the one who inflicted the injuries. At times, again, the medical evidence is confined to the fact that the condition of the parts examined is consistent with the female in question having had sexual intercourse at some time or other with a male person, and this circumstance, which obviously may be present when a woman has made a baseless charge against an innocent man, may weigh heavily against him in the minds of an uneducated and possibly prejudiced jury. The corroboration of the story of a prosecutrix in charges of unlawful carnal knowledge and indecent assault by evidence which is, strictly speaking, relevant to the issue to be tried may be difficult and in many instances impossible to obtain. This, however, is no reason why one person should be convicted of crime upon the unsupported word of another. If in the proof of material allegations a case is found to be one of "oath against oath" there can be no logical reason why the oath of the complainant should prevail over that of the person complained against if we assume each to enjoy equal good fame. It may be granted that one of two, the accuser or the accused, must be swearing falsely, but it must be remembered that if a charge of perjury were to be made in such circumstances no conviction would follow, for the unsupported oath of one man will not suffice at law to convict another of perjury. Two convictions for sexual offences upon the testimony of women which was not corroborated by any direct evidence have recently been referred to in THE LANCET.[1] In both of these the verdicts were arrived at with difficulty, owing to the divergent opinions formed by jurymen, and in neither of them was the trial held before a judge of the High Court of Justice. In particular the attention of the medical profession has been attracted by that of Mr. William Herbert Ray at Margate Quarter Sessions, in which the corroboration appears to have been reduced to the smallest possible dimensions. It may not be too late for the circumstances of this case to be examined by the Home Secretary and for the peculiar danger which it reveals to be very carefully considered by him. It may be regarded as typical of the risks to which medical men are daily subjected and for the avoidance of which no means appear to exist. It is hardly practicable for them to have third persons present at all their interviews with female patients, and unless some outcry is alleged to have been made, which must have been heard had it taken place, it is almost impossible for the accused to call any contradictory evidence other than his own. It is admittedly of the utmost importance that women should be protected from criminal acts and that those who commit such acts should be punished. Many criminals, however, escape conviction for all sorts of offences in the course of every year, and it is always reckoned as better that this should be the case than that there should be any risk of any innocent person being included among the guilty. In the case of sexual offences the danger of error is greater than when other criminal charges are brought, and when these offences are alleged against medical men the danger is immeasurably increased by the circumstances to which we have called attention.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8134 births and 4608 deaths were registered during the week ending April 18th. The annual rate of mortality in these towns, which had been 16·2, 15·8, and 15·6 per 1000 in the three preceding weeks, rose again to 15·9 per 1000 last week. In London the death-rate was 16·1 per 1000, while it averaged 15·9 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 7·8 in Croydon, 10·0 in Hornsey, 10·3 in Willesden, 10·4 in Stockport, 10·5 in Aston Manor, 10·6 in Barrow-in-Furness, 10·7 in Wallasey, and 10·8 in Coventry; the highest rates were 19·5 in Brighton, 19·7 in Bootle and in St. Helen's, 19·9 in Blackburn, 20·0 in Rhondda, 22·4 in Swansea, 23·5 in Wigan, and 24·4 in Sunderland. The 4608 deaths in these towns last week included 454 which were referred to the principal infectious diseases, against 489, 465, and 454 in the three preceding weeks; of these 454 deaths 165 resulted from measles, 91 from whooping-cough, 64 from diphtheria, 55 from diarrhœa, 34 from "fever" (principally enteric), 27 from scarlet fever, and 18 from small-pox. In 13 towns, including Brighton, Southampton, Northampton, Norwich, Derby, Stockport, Halifax, and eight other smaller towns, no death from any of these diseases was registered last week; while the highest death-rates from these principal infectious diseases were recorded in Tottenham, West Bromwich, St Helen's, Wigan, Rochdale, Burnley, Middlesbrough, Rhondda, and Swansea. The greatest proportional mortality from measles occurred in Tottenham, West Bromwich, Nottingham, Wigan, Manchester, Burnley, Middlesbrough, and Swansea; from scarlet fever in Rochdale, from diphtheria in Hanley, Walsall, Oldham, and Middlesbrough, from whooping cough in Tottenham, Portsmouth, Reading, St Helen's, Oldham, Rochdale, and Burnley, from "fever in Rhondda, and from diarrhœa in St Helen's Seven fatal cases of small pox were registered in Liverpool, three in Leeds, and one each in Croydon, Leicester, Manchester, Oldham, Rochdale, Bradford, Rotherham, and Cardiff, but not one in any other of the 76 large towns The number of small pox patients in the Metropolitan Asylums hospitals, which had risen from five to 16 at the end of the seven preceding weeks, had further risen to 33 at the end of last week, 22 new cases were admitted during the week, against five three, and five in the three preceding weeks The number of scarlet fever cases under treatment in these hospitals and in the London Fever Hospital on Saturday last, April 18th, was [illegible] from 1798 to 1664 on the five [illegible] cases were admitted during [illegible] d 158 in the three preceding [illegible] diseases of the respiratory organs in London, which had been 250, 238, and 234 in the three preceding weeks, rose again last week to 262 but were 36 below the number in the corresponding week of last year The causes of 61, or 1 3 per cent, of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Croydon, West Ham, Bolton, Salford, Bradford, and 45 other smaller towns, the largest proportions of uncertified deaths were registered in Willesden, Birmingham, Smethwick Liverpool, Warrington, Sheffield, and Middlesbrough

---

[1] THE LANCET, Jan. 31st, 1903, p. 344, and March 14th, 1903, p. 749.

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in eight of the principal Scotch towns, which had been 18 6, 18 0, and 17 6 per 1000 in the three preceding weeks, rose again to 17 7 per 1000 during the week ending April 18th, and was 1 8 per 1000 in excess of the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 7 7 in Perth and 11 8 in Leith to 19 5 in Greenock and 20·3 in Edinburgh The 681 deaths in these towns last week included 17 which were referred to whooping-cough, 17 to diarrhœa, eight to diphtheria, seven to measles, two to scarlet fever, and two to "fever," but not one to small pox. In all 53 deaths resulted from these principal infectious diseases last week, against 77, 57, and 64 in the three preceding weeks These 53 deaths were equal to an annual rate of 1 6 per 1000, which was also the mean rate last week from the same diseases in the 76 large English towns The fatal cases of whooping cough, which had been 25 in each of the two preceding weeks, declined last week to 17, of which 11 occurred in Glasgow, three in Edinburgh, and two in Dundee The deaths from diarrhœa, which had been 17, 14, and 11 in the three preceding weeks, rose again to 17 last week, and included nine in Glasgow, three in Aberdeen two in Edinburgh, and two in Greenock The fatal cases of diphtheria, which had been three, one, and three in the three preceding weeks, further rose last week to eight of which four were registered in Glasgow and two in Edinburgh The deaths from measles, which had risen from eight to 14 in the four preceding weeks, declined again to seven last week, and included three in Aberdeen, two in Edinburgh, and two in Dundee The mortality from scarlet fever and from "fever' showed a decline in each case from that recorded in the preceding week. The deaths referred to diseases of the respiratory organs in these towns, which had been 100, 121, and 93 in the three preceding weeks rose again last week to 109 and were 90 below the number in the corresponding period of last year The causes of 20, or more than 3 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 29 3, 27 1, and 2[illegible] eeks, rose again last [illegible] past four weeks the d[illegible] the rates during the same period being 16 9 in London and 18 9 in Edinburgh. The 178 deaths of persons belonging to Dublin registered during the week under notice were six in excess of the number in the preceding week and included six which were referred to the principal infectious diseases, against 18, 15, and 16 in the three preceding weeks, of these, two resulted from scarlet fever, two from "fever," one from small pox, and one from whooping cough, but not one from measles, from diphtheria, or from diarrhœa. These six deaths were equal to an annual rate of 0 8 per 1000, the death rates last week from the same diseases being 1 7 in London and 1 6 in Edinburgh The fatal cases of scarlet fever, which had been two, two, and one in the three preceding weeks, rose again to two last week The deaths from "fever," which had been three, two, and four in the three preceding weeks, declined again last week to two In each of the last four weeks one fatal case of small pox has been registered The 178 deaths in Dublin last week included 29 of children under one year of age and 48 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a slight decline from the respective numbers recorded in the preceding weeks Four inquest cases and five deaths from violence were registered, and 59, or nearly one third, of the deaths occurred in public institutions The causes of six, or more than 3 per cent., of the deaths in Dublin last week were not certified

VITAL STATISTICS OF LONDON DURING MARCH, 1903

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 5 9 per 1000 of the population, estimated at 4,613 812 persons in the middle of the year In the three preceding months the rates had been 7 4, 6 5, and 6 2 per 1000 respectively The rates were considerably below the average in Paddington, Hampstead, Stoke Newington, Finsbury, Greenwich, and Woolwich, while they showed the largest excess in Hammersmith, Fulham, St Pancras, Hackney, Bermondsey, Wandsworth, and Deptford The prevalence of small pox showed a slight decline from that recorded in the preceding month, of the 13 cases notified during the month, three belonged to Chelsea, three to Stepney, two to Bermondsey, two to Camberwell one to Finsbury, one to Battersea, and one to the "Port of London The Metropolitan Asylums hospitals contained 13 small pox patients at the end of March, against 14 seven and five at the end of the three preceding months, the weekly admissions averaged three, which was the average weekly number in each of the five preceding months also The prevalence of scarlet fever showed a slight increase over that recorded in the preceding month, *this disease* showed the highest proportional prevalence in Fulham, Bermondsey, Wandsworth, Deptford and Lewisham The number of scarlet fever patients in the Metropolitan Asylums hospitals, which had been 2327, 1980, and 1820 at the end of the three preceding months, had further declined to 1704 at the end of last month, the weekly admissions averaged 208 against 236, 212, and 205 in the three preceding months The prevalence of diphtheria showed a slight decline from that in the preceding month, among the various *metropolitan boroughs this disease was* proportionally most prevalent in St. Pancras, Hackney, Bethnal Green Southwark Wandsworth and Deptford There were 903 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 981 936 and 1030 at the end of the three preceding months, the weekly admissions averaged 126, against 136, 131, and 152 in the three preceding months The prevalence of enteric fever last month showed a further decline from that recorded in recent months, the greatest proportional prevalence of this disease occurred in Kensington, Hammersmith City of Westminster, Bermondsey, Wandsworth Deptford and Greenwich. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 210, 172 and 125 at the end of the three preceding months, had further declined to 92 at the end of March, the weekly admissions averaged 15 last month, against 30, 22, and 13 in the three preceding months Erysipelas was proportionally most prevalent in Hammersmith, Holborn, Finsbury, Shoreditch, Bethnal Green, and Battersea The 18 cases of puerperal fever notified during

the month included four in Fulham, two in St. Pancras, and two in Finsbury.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in public institutions having been distributed among the several boroughs in which the deceased persons had previously resided. During the five weeks ending April 4th the deaths of 7025 persons belonging to London were registered, equal to an annual rate of 15·9 per 1000, against 18·2, 18·2, and 16·5 per 1000 in the three preceding months. The lowest death-rates last month in the various metropolitan boroughs were 11·5 in Lewisham, 11·8 in Hampstead, 12·3 in Fulham, 12·9 in Paddington, 13·1 in Wandsworth, 13·2 in Deptford, and 13·6 in Woolwich; the highest rates were 19·0 in Bermondsey, 20·3 in Southwark, 20·8 in Poplar, 20·9 in Shoreditch, 21·1 in Holborn, and 22·0 in Finsbury. The 7025 deaths from all causes included 850 which were referred to the principal infectious diseases; of these, two resulted from small-pox, 336 from measles, 31 from scarlet fever, 97 from diphtheria, 264 from whooping-cough, one from typhus, 21 from enteric fever, and 98 from diarrhœa, but not one from simple continued fever. The lowest death-rates from these principal infectious diseases were recorded in Paddington, Fulham, Chelsea, City of Westminster, City of London, Lewisham, and Woolwich; and the highest rates in St. Pancras, Islington, Stoke Newington, Shoreditch, and Poplar. The two fatal cases of small-pox belonged to Stepney. The 336 deaths from measles were slightly in excess of the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in St. Pancras, Stoke Newington, Shoreditch, Bethnal Green, Stepney, and Poplar. The 31 deaths from scarlet fever were only one half of the average number in the corresponding periods of the ten preceding years; this disease showed the highest proportional fatality in City of Westminster, St. Marylebone, Bermondsey, Deptford, and Lewisham The 97 fatal cases of diphtheria showed a decline of 102 from the corrected average number; among the various metropolitan boroughs diphtheria was proportionally most fatal in Hampstead, Bethnal Green, Poplar, Southwark, Wandsworth, Camberwell, and Deptford. The 264 deaths from whooping-cough were slightly below the average number in the corresponding periods of the ten preceding years; this disease showed the highest proportional fatality in Kensington, Chelsea, St. Marylebone, St. Pancras, Islington, and Poplar. The 22 deaths referred to "fever" showed a decline of 21 from the corrected average number; among the various metropolitan boroughs the highest fever death-rates were recorded in Paddington, Holborn, Southwark, Battersea, and Greenwich. The 98 fatal cases of diarrhœa were considerably in excess of the average; the highest proportional fatality from this disease was recorded in Kensington, St. Marylebone, Islington, Holborn, Lambeth, Wandsworth, and Camberwell. In conclusion, it may be stated that the aggregate mortality from these principal infectious diseases in London last month was more than 14 per cent. below the average

Infant mortality in London last month, measured by the proportion of deaths among children under one year of age to registered births, was equal to 125 per 1000. The lowest rates of infant mortality were recorded in Paddington, Hampstead, Hackney, Bermondsey, Deptford, and Lewisham; and the highest rates in Kensington, Hammersmith, City of Westminster, Stoke Newington, and City of London.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeon J. D. Hughes to the *Pioneer*. Surgeon A. D. Spalding to Chatham Hospital, lent Civil Practitioner W. E. Munro to be Surgeon and Agent at Burghead.

ARMY MEDICAL SERVICE.

Major and Brevet Lieutenant-Colonel M. W. H. Russell, R.A.M.C., to be a Deputy Assistant Director-General, on augmentation. Dated April 1st, 1903.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel W. A. May, C.B., to be Colonel, vice J. P. Rooney, retired. Dated March 22nd, 1903.

The undermentioned officers were promoted for service in South Africa, and not as stated in the *Gazette* of Feb. 24th, 1902:—Army Medical Staff: Colonel F. W. B. Hodder, retired pay, and Major H. L. G. Chevers, retired list. (*London Gazette*).

IMPERIAL YEOMANRY.

Royal 1st Devon: Surgeon Lieutenant M. B. Steuart resigns his commission. Dated April 22nd, 1903. North Somerset: Surgeon-Lieutenant J. G. D. Kerr resigns his commission. Dated April 22nd, 1903

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion the Queen's Own (Royal West Kent Regiment): Surgeon-Lieutenant G. R. F. Stilwell to be Surgeon-Captain. Dated April 22nd, 1903. 2nd Volunteer Battalion the York and Lancaster Regiment.

DEATHS IN THE SERVICES

Brigade-Surgeon Richard Thomas Lyons, I.M.S. (retired list), suddenly at his residence, Scrope-terrace, Cambridge, from angina pectoris, in his sixty-eighth year. He joined the army in 1860 and served in the Umbeyla Campaign, 1868, and was present at the forcing of the Pass and at the defence of Eagles' Nest picquet (mentioned in despatches, medal with clasp). He took part in the Lushai Expedition of 1870, in the Afghan War, 1878–79 (medal with clasp), and served with the Suakim Expedition of 1885 (medal, clasp, and bronze star).

Deputy Surgeon-General George Bankes Floyer Arden, A.M.D. (retired list), suddenly on April 1st at sea on board the *Zweena*. After joining the army as assistant surgeon he became surgeon in 1866, and retired with the honorary rank of deputy surgeon-general in 1879. He served with the 12th Regiment in the New Zealand War from July, 1863, to June, 1866 (medal).

Deputy Surgeon-General Joseph Furlonge Shekleton, I.M.S (retired), at his residence, Victoria-square, Clifton, on April 15th in his eighty-third year. The deceased entered the Indian Medical Service in 1845 and served with the 3rd Troop Bombay Horse Artillery in the Punjab Campaign of 1848–49, being present at the siege of Multan and the battle of Guzerat, for which he received the medal and two clasps. He subsequently qualified for the Assay Department and was assay master and acting mint master at Calcutta. After his retirement he lived at Clifton [illegible] was for about eight years secretary and house [illegible] to the Bristol Royal Infirmary. The deceased [illegible] valuable service to that institution and up to the time [illegible] death he took a great interest in all things connected [illegible]

FOREIGN DEPARTMENT.

ANALYSIS OF FOREIGN MEDICAL JOURNALS.
REVUE MEDICALE—FEVRIER.

A remarkable case of Poisoning by Prussic Acid, with some Observations on the employment of Ammonia as a remedy.

Towards the latter end of August, M. B., a physician of Rennes, of a strong constitution, prepared some hydrocyanic acid, and was induced to take a portion, from which he felt no inconvenience. On the 3d of September following, at 11 o'clock in the morning, he took in some coffee almost a tea-spoon full of the prussic acid, prepared according to the method of Scheele. He found this stronger than his own, but still it had no material effect. At one he dined, and about seven o'clock in the evening he again took the same quantity as before, prepared by M. Delonde. He found this stronger than the preceding, but said, "Still it has no effect." He immediately left the apartment where he made this experiment, but scarcely had he advanced three steps in the street, when he felt a sort of shock in the head, which he considered as the precursor of some mischief. He collected himself, and said, "*Ma Foi*, it has done something ! Give me ——" and immediately fell, as if thunderstruck. *The first symptoms* were sudden cessation of the intellectual powers, trismus, difficult respiration, followed by cold extremities and stertorous breathing ; an odour of bitter almonds exhaled from, and distortion of, the mouth ; pulse scarcely perceptible at the left, but much stronger at the right wrist ; the face discoloured and swollen ; pupils fixed and dilated ; in short, in every respect similar to a man in the last stage of apoplexy. *Frictions, with the tincture of cantharides, and pure ammonia ; compresses soaked in the same mixture ; and large sinapisms were applied.*

The trismus increased, until at length a convulsive action took-place, greatly resembling opisthotonos, which lasted for some minutes. An iron spoon was slipped between the teeth, and, by means of a small opening, a feather was introduced as far as the throat ; this stimulus excited nausea, and some black mucus was vomited. The essential oil of turpentine in some coffee was then given. Ice was also applied to the head. This treatment was persevered in for two hours and a half, when the patient evinced some return of his senses by the following words, "*I have taken prussic acid—I recommend my son to you—give me air, and let me die.*" He likewise recognised some friends surrounding him. The intellectual faculties returned by degrees. There still existed a considerable dyspnœa ; sinapisms were applied, and a strong purgative enema administered, on the action of which, a large quantity of flatus was disengaged, strongly impregnated with the odour of prussic acid.

By six in the morning he was capable of being removed to his own house. On the 4th, slight febrile symptoms came on ; he also complained greatly of his mouth, which was intensely inflamed, and much ulcerated. Inflammation of the lungs supervened, but which was eventually removed, and on the sixteenth day after the accident, he was enabled to walk out ; and at present enjoys even better health than before the accident.

From the above circumstance it is evident that the prussic acid of the shops varies not only with respect to the intensity and rapidity with which it diffuses its baneful principles, but very probably in its component parts. In fact, M. D. tells us, that four drops of the acid prepared according to Scheele, had no other effect on him, than a sensation of constriction about the upper part of the pharynx, whilst the mere inspiration from a flask containing the acid which M. B. took, occasioned a great irritation about the top of the nasal passages, accompanied with pain in the head, and giddiness ; alcohol and pure *ammonia* immediately removed it. Dr. Murray has also found that ammonia, in the dose of a few drops, instantly dispels the severe headaches incident to those persons working in the laboratories where the prussic acid is made. This acid appears to act suddenly on the brain, by suspending the nervous influence, while the nerves of the spine still continue to act. It besides effects the organs of respiration, since the most formidable symptoms were those of very great oppression in breathing ; suppression of urine also lasted for four days.

From the impossibility of deglutition, M. D. recommends the introduction of a gum elastic sound into the nasal passages, through which the counter poison could be received in the stomach. He concludes by observing, too much care cannot be taken in selecting a medicine of such powerful and varied strength.

THE DANGER OF SELF-MEDICATION WITH TABLOIDS.

To the Editors of The Lancet.

Sirs,—The case of acute trional poisoning recorded in The Lancet of April 18th, p. 1096, is one which has very practical lessons, not only for the public, but also for the profession, at the present time. I have always maintained that the tabloid form of medicine was a snare and a delusion. Put up, as these products are, in beautifully designed bottles with labels bearing the prescription and directions in the plainest of English, they naturally aid the laity in self-treatment. Time after time I have been called to attend ladies who were suffering from the effects of what one must call "tabloid poisoning" for want of a better generic term. Sulphonal, opium, digitalis, strychnine, and thyroid extract are but a few of the drugs which I have found patients taking themselves in the form of tabloids and prescribing right and left to their friends.

If the medical attendant is so foolish as to order a bottle of tabloids for any particular patient he may rest assured that his patient will in future prescribe for himself and cease to trouble his medical adviser. It is all very well to say that the chemist always removes the tabloids from the original bottle and puts them up in a plain box with the physician's directions written on an ordinary stock label. The patient, somehow or other, soon finds out the name of the tabloids he is getting and also that he can obtain them more cheaply by going to a drug-store and purchasing a bottle of 25 or 100. The patient referred to in the case described in your columns knew that she was taking trional and also that from one to six tabloids was a dose. But surely 30 grains of trional are more than an average amount. We find that she had taken "two or three of the tabloids once before," and that she "thought they were quite harmless things." Time after time have I been told the same thing by patients who had been taking tabloids of thyroid extract with disastrous results.

Surely in view of the facts which I have stated we, as a profession, should discountenance the prescribing of tabloids for patients. If we cannot write prescriptions in the orthodox way it is high time we ceased to exist as a profession. I, for one, have never at any time ordered tabloids and never intend doing so. It would be interesting to have the opinion of the leading members of our profession on the subject, but meantime I trust that those who read the case of trional poisoning will bear it in mind as a lesson and a warning against the prescribing of such dangerous products as tabloids.

I am, Sirs, yours faithfully,
James Burnet, M.A., M.B., M.R.C.P. Edin.
Edinburgh, April 18th, 1903.

THE RISE OF BLOOD PRESSURE IN LATER LIFE.

To the Editors of The Lancet.

Sirs,—In his letter to The Lancet of March 28th, p. 920, Professor T. Clifford Allbutt says : "The pressure in any one capillary is, of course, infinitely small." He estimates the mean capillary pressure as about 50 mm. Hg and is therefore presumably using the term "pressure" in the ordinary sense as implying the force exerted per unit area, since this is the only sense in which pressure can be estimated by the height of a column of fluid If we use the term "pressure" in this sense it is impossible that the pressure in any individual capillary should be infinitely small, since it must be greater than that in the vein into which the capillary opens as otherwise there could be no flow of blood from the capillary into the vein The pressure in any individual capillary in a given area is the same as the mean capillary pressure for that area If, then, the mean pressure in a given area is 50 mm Hg the pressure in any individual capillary will, allowing for local variations, be of the same amount I venture to think that Professor Allbutt has misunderstood Dr Harry Campbell Dr Campbell *refers to capillary resistance and not to the pressure* As I understand Dr Campbell this capillary resistance is not the pressure but is the amount by which the pressure is lowered during the passage of the blood through the capillaries

OPERATION IN SUPPURATIVE DISEASES OF THE EAR

To the Editors of THE LANCET

SIRS —I have read with much interest Mr Charles A Ballance s paper as published in THE LANCET of April 11th p 1010 I do not propose to criticise his operation which he has taken such trouble to perfect I certainly agree with him that it is not for everybody to attempt I should be glad, however, if you would allow me to express a doubt as to whether all his opinions in this matter of suppurative otitis are well founded For a good many years I have devoted a considerable proportion of my time to the study of this disease and I know that the large majority of cases may be cured by treatment through the meatus if sufficient skill and attention be given. I have published from time to time some of the results of my system of antiseptic irrigation of the ear Further experience has confirmed my opinion as to its general efficacy, though I have found it necessary in certain cases to remove by operation the remains of the membrane which may be an obstacle to free irrigation I had doubts at first as to the safety of this proceeding but I find that the complete removal produces little or no disturbance in these cases I remove the membrane as completely as possible with the malleus and in some cases curette the attic And here I am at direct issue with Mr Ballance After the numerous operations which I as well as others have performed without any serious symptom having arisen I cannot agree with Mr Ballance s opinion that "such measures as curetting away granulations removal of ossicles polypi &c , are not only inefficient but dangerous In face of so much professional indifference to and ignorance of, ear diseases such a statement from a well known man may do a great deal of harm But we are to swallow the camel in the five hour operation of Mr Ballance and at the same time to reject the gnat in the common sense and often absolutely necessary minor operation of ten minutes duration As to the inefficiency of operations through the meatus, I can only say that 'I have been able to cure by such means several cases that had been under prolonged treatment by specialists without relief It is certainly true that there has been much inefficient treatment of the ear both with the syringe and the curette—and the same may be said of treatment with burr and chisel I have before now pleaded for more thorough methods and close personal supervision. Some of my cases are attended to three or four times a day and the *out-patients attend at the hospital daily for irrigation* These cases are kept under constant observation and therefore my statement that I have never observed extension of disease to the bone in case under irrigation should carry some weight. But passing on to cases in which through neglect the bone has already been diseased I think that each case should be studied on its own merits or demerits and that a routine resort to the complete operation is to be deprecated *I have certainly seen a good many cases recover after* what I am afraid Mr Ballance would call very partial operations and I can remember very few indeed which seemed to require the drastic removals advocated by Mr Ballance And after the most elaborate and exhausting of these radical operations the surgeon can never be sure that he has removed all disease In any case he will have to rely for cure on the vitality of the tissues which he has been good enough to leave Tissue vitality, when assisted by antiseptic irrigation, will sometimes effect what the boldest surgeon dare not attempt I have on four occasions removed the remains of the exfoliated cochlea through the meatus with large portions of the *petrous bone Three of these cases recovered* The fourth succumbed to whooping cough and pneumonia when nearly recovered of his ear disease

I am, Sirs, yours faithfully,
April 21st F FAULDER WHITE

THE BATTLE OF THE CLUBS

To the Editors of THE LANCET

SIRS,—With regard to an able article which appeared recently in THE LANCET by your special correspondent on the important subject of the organisation of the medical profession, more especially in the mining districts of South Wales, I consider the well written article an issue of the greatest value and importance to all medical practitioners in works districts I was in hope that such would have been commented upon by a senior medical practitioner in South Wales We, the medical practitioners in the mid districts of the Swansea valley, cordially met to arrange proposals for new conditions and methods of organisation We made an application to the chairman of the works committee of the various works also to the chairman of the directors, asking him to allow the clerk to deduct 3*d* in the pound of wages received under the old Surgeon's Truck Act in accordance with lists supplied by our collectors, for professional attendance upon the colliers and their families We, moreover, get an extra fee for midwifery cases and find no difficulty to obtain extra fees for such attendance. Previously medical fees were paid very unequally at different works for our professional services I may mention that I have only been two years in practice here and I was from the first very dissatisfied with such a method of payment Unfortunately, our application did not at first meet with the approval of the workmen, who turned out of one of the collieries one day owing to this matter , upon further consideration they returned to their work the following morning with the result that a deputation called upon one of the senior medical practitioners requesting that the medical fees should remain as before We would not con-
sent to any suc were
successful on all owing
to there being th of the
colliers The able article which recently appeared in your

JACOBI'S ATLAS OF SKIN DISEASES—SMALL-POX AFTER VACCINATION · A CORRECTION

To the Editors of THE LANCET

SIRS —As the English translation of the above work is obtaining a considerable circulation in this country (which the general excellence of the plates fully justifies) I feel it is my duty, in the true interests of vaccination, to correct an unfortunate and inexplicable misstatement which appears under the heading of ' small pox Such an error in so important a work is calculated, if uncorrected, to lead to serious misapprehension

The representations of small pox in the work consist chiefly of reproductions of photographs six in number , the first four being of severe unmodified cases and the last two of very mild and highly modified cases In the letterpress, after the description of the first four photographs appears the following extraordinary statement (p 62) —'Although variola may undoubtedly occur occasionally in persons, who have been vaccinated with apparent success the disease is invariably modified and never assumes the more severe type illustrated in the preceding photographs. The rash is always scanty and sparse in distribution and the lesions soon dry up to form small brownish scabs.'

It is scarcely necessary to point out that such a statement is quite at variance with the real facts and although a defective knowledge of small-pox may be excusable in a German author it is certainly surprising that an English translator should have passed the statement without comment. That it was allowed to pass, however, seems to indicate that amongst medical men who have not had much practical experience of small-pox there is a somewhat exaggerated idea of the efficacy of vaccination. It is fully recognised nowadays that the protection conferred by vaccination lapses after a variable number of years and that too often small-pox, if then contracted, assumes an unmodified and possibly fatal form. I have myself seen confluent and entirely unmodified small-pox only ten years after vaccination, but such cases are fortunately very rare and quite exceptional. 20 years after vaccination, however, unmodified small-pox is by no means uncommon.

As regards the illustrations themselves, they are reproductions of photographs taken by me in the Birmingham epidemic, 1892–95. It is to be regretted that the author did not communicate with me before making use of them. He could then at least have made sure that he had the facts relating to them correctly. As it is, he states concerning the unmodified cases: "None of the four cases depicted were protected by vaccination," which statement, taken literally, is obviously quite true. But if the author intends to imply (as from the context it is clear that he does) that none of them had ever been vaccinated, then he is certainly in error. I have looked up my original photograph of Case xxxv. B. 1, which he describes as "an extremely severe case of confluent small-pox in a man, aged 23, on the tenth day of the disease," and I find the following note written on the back: "Ernest S——, 23 years, vaccinated, four marks, fair size and foveation; photo taken tenth day." I remember the case quite well as the poor fellow remained in hospital for an unusually long time owing to serious complications. The value of vaccination in conferring protection against small-pox *for a time* has been so completely established as to be beyond the pale of scientific controversy, but reckless statements such as the one in question in a presumably scientific work can only bring the operation into the gravest disrepute and go far to explain the bitterness of those who are opposed to it.

I am, Sirs, yours faithfully,

Town Hall, Leicester, April 6th, 1903. C. Killick Millard.

CONTRACT PRACTICE IN THE COUNTY OF DURHAM.

To the Editors of The Lancet.

Sirs,—For four years a struggle has been going on in the county of Durham to obtain increased remuneration for medical attendance on the miners. In some places the higher rate has been easily obtained, in other places there has been delay, whilst in a few places the struggle has been somewhat keen. At the present time in the outskirts of the cathedral city of Durham a very strong and bitter spirit is shown by the miners of this district. Having stoutly rejected the demand made by the local practitioner who had served the miners so well for some eight years, they obtained the services of an outsider; they canvass for him, they coerce their fellow-men to become his patients, and they sing his praises in every cottage; but after a time certain events happen which demonstrate very clearly that the skill displayed by the outsider is not all that may be desired.

The County of Durham Medical Union has quietly and very certainly made up its mind not to associate in any way with a medical man who tramples under foot all that is honourable in the profession. This union is heartily supported by all the consultants of the north of England. When miners strike for more pay and any men are found who are ready to work at the lower rate, they are dubbed "blacklegs," and are likely to be treated with much violence by those on strike. Medical men cannot resort to violence towards those who are willing to take the lower rate of pay (and so take away the practice of a medical man), but the only course they can adopt is to hold aloof as a body and a union and not in any way to associate with one who has lost all dignity and honour. The miners in this particular instance would fain compel the medical union to recognise and associate with the man of their choice without any regard to principles.

In the year 1899 I sent a printed appeal to the medical schools of Scotland and the North of England pointing out that a struggle was going on in the county of Durham for increased remuneration and we trusted to the dignity and uprightness of our brethren in the profession not to take advantage of the offers made by the miners. We think that this appeal was noticed in some way; at any rate, we have been assured that the students readily grasped the situation and expressed a loyal feeling. It is, however, disappointing to find that there are practitioners still existing who wish to be informed as to the principle involved; that if the miners should after a time give 9*d.* instead of 6*d.* per fortnight to the man introduced by them no opposition need be continued; that the dispute is now at an end. But this is not so; the dispute is not ended until the old practitioner is reinstated and the proper remuneration is settled. Again, some ask how long must this condition of strife continue. Our reply to this is the same as stated above—viz., so long as the old practitioner is opposed and the proper remuneration is withheld.

I have written all this at some length in order to explain clearly our position, and trusting to the good spirit of your readers that we shall have the help and sympathy of the whole of the profession.

I am, Sirs, yours faithfully,
Edward Jepson,
President, County of Durham Medical Union.

Durham, April 15th, 1903.

BLISTERING IN CHRONIC SKIN DISEASES.

To the Editors of The Lancet.

Sirs,—Dr. G. Norman Meachen[1] has kindly given the information which I failed to obtain from the latest dermatological text-books in my possession. I was not aware until now that vesication had ever been attempted with a view to eradicate psoriatic patches. It might interest Dr. Meachen to know that patient No. 3[2] is still under treatment by vesication, and that during the past fortnight several commencing patches of psoriasis on the face, back of hand, and at junctions of the ear and scalp have disappeared after *one* good blistering. When a patch is large and to all appearance stationary, it seems that liquor epispasticus has to be applied on two or three occasions ere any blistering effect is produced. I may add, in conclusion, that there has been no recurrence of psoriasis on any of the areas cleared by vesication.—I am, Sirs, yours faithfully,

John Wishart, M.B., Ch.B., B.Sc. Aberd.

Bedlington, R.S.O., April 18th, 1903.

ETHYL CHLORIDE.

To the Editors of The Lancet.

Sirs,—I wish to correct an omission in the printing of my article on ethyl chloride in The Lancet of April 4th, p. 952. The shortest case of anæsthesia in the 77 dental cases is stated to be 3 seconds, whereas really it was *30* seconds. This is an important difference. Perhaps I may be allowed to say that Messrs Duncan and Flockhart are now making pure ethyl chloride, free from methyl chloride, for inhalation. Thanking you in anticipation, I am, Sirs, yours faithfully,

Birmingham, April 20th, 1903. W. J. McCardie.

⁂ It will be seen on close inspection that the apparent error was due to a failure of the character 0 to print and not to its being left out.—Ed. L.

A PROTEST AGAINST *DIRT.*

To the Editors of The Lancet.

Sirs,—In these days, when the sterilisation of everything from milk to toothpicks and postage stamps is demanded, it gives one pause to notice the small concern there seems to be for cleanliness as opposed to filth. I allude to the absolutely disgusting circumstances attending the delivery of food in London. Meat and fish are frequently carried on open platters exposed to dust and dirt of all kinds. Bread is put in a basket slung over the carrier's shoulder, where it rubs against his not too clean coat. If he wishes to rest the basket is put down and for the better comfort of the carrier he sits in it, bread and all. The other day I saw an elaboration of this method, the boy sitting upon a loaf which he had taken from the basket and placed on the pavement. I may be faddy but I do not think I would want that loaf. To-day I saw a basket of rhubarb and green vegetables left on the sidewalk while the boy in charge of it was down an area. A dog coming along realised his opportunities and took full advantage of them. As in the case of the loaf, I would prefer not to eat those vegetables.

---

[1] The Lancet, April 18th, p. 1126.
[2] The Lancet, April 11th, p. 1030.

Now these things are quite avoidable and should be prevented. Surely if in some cases meat and fish must be delivered on an open platter the articles might be wrapped in clean brown paper before leaving the shop. Shopkeepers might be a little more particular about their errand boys; and, above all, if the public expressed a decided preference for having their food delivered in a clean and decent manner they would soon have it so. In the cooking no doubt the risk of microbic infection is reduced to a minimum, but I am not inveighing against microbic dangers but against dirt—easily avoidable, entirely unnecessary *dirt*.

I am, Sirs, yours faithfully,
FREDERICK R. WAINWRIGHT.
Kensington Park-gardens, W., April 18th, 1903.

A SUGGESTION FOR THE MORE EFFICIENT CONTROL OF THE FOUL AIR OF SMALL-POX HOSPITALS.

To the Editors of THE LANCET.

SIRS,—In consequence of the increasing difficulty in finding suitable and convenient sites for the erection of small-pox hospitals and of the increasing alarm with which they are regarded by the inhabitants in the neighbourhood of their proposed erection the feasibility has occurred to me of a system of below-the-surface-level or underground wards, bath-, dressing-, and disinfecting-rooms, ventilated by an up-cast shaft and furnace, which in spite of some obvious drawbacks I still venture to bring forward. (The spent air might also be screened before passing through the furnace.) The other buildings, including a nurses' block (living- and sleeping-rooms), would be above ground as at present

A further question also arises on the score of economy and convenience: the possibility of building, within the same inclosure on the outskirts of a town, a fever hospital and small-pox wards (underground) worked by a central administrative block and staff, the nursing staffs, of course, being kept separate and distinct.

I am, Sirs, yours faithfully,
Preston, April 20th, 1903. WALTER F. MOORE.

TROPHIC AREAS AND THE INCIDENCE OF CARCINOMA.

To the Editors of THE LANCET.

SIRS,—From the report of the meeting of the Pathological Society of London [illegible] that I inferred that in s[illegible] by Mr. G. L. Cheatle the [illegible] of more importance as a [illegible] epithelial growths than the distribution of nerves and trophic areas. What I intended to convey was that it seemed to me in many instances of rodent growth about the face, and possibly elsewhere, that congenital clefts might be a factor of incidence, while nerve distribution might be a factor of limitation of extension. I see no reason why in this particular growth these two factors should not go hand in hand. I much regret that Mr. Che[illegible]ing to my suggestion.

Harley street, [illegible] ECCLES.

*** The following are the remarks in reply which Mr. Cheatle would have made had he had the opportunity of speaking.—ED. L.

MR. CHEATLE'S REPLY.

I presume that any epithelial cell is a possibl[illegible]

[illegible]

same time I admit that some of the cancers in these cases appeared in the position of clefts, but there were also cancers which originated where no clefts existed. I make no statement as to whether cancers [illegible] clefts than else- [illegible] the cell or cells [illegible] ndirect nervous [illegible], and this apart from all influence upon the spread of cancer.

THE SURGICAL TREATMENT OF PUERPERAL PYÆMIA.

To the Editors of THE LANCET.

SIRS,—I have read Mr. E. Michels's paper on the Surgical Treatment of Puerperal Pyæmia in THE LANCET of April 11th, p. 1025, with very great interest, as it is the first case reported in England that realises a suggestion of mine—viz., the ligature of the thrombosed vein in such circumstances. In 1898 I published a paper on Intravascular Coagulation in the Edinburgh Hospital Reports and in it the following remark was made: "During the earlier stage, in some cases of sepsis after labour or abortion, would it be practicable to explore the iliac veins and apply a ligature, as has been done so successfully in the case of septic thrombosis of the internal jugular vein?" This question has doubtless occurred to many others and everyone must congratulate Mr. Michels on the successful termination of the first case in this country.

I am, Sirs, yours faithfully,
Cambridge. J. CHRISTIAN SIMPSON, M.D. Edin.

THE CASE OF MR. J. W. AYRES.

To the Editors of THE LANCET.

SIRS,—Your readers will doubtless remember well the case of Mr. J. W. Ayres, L.R.C.P. Edin., L.S.A., of Farnworth-street, in this city. In the spring of 1902 Mr. Ayres was convicted of manslaughter and was sentenced to four months' imprisonment. Despite this conviction the General Medical Council allowed Mr. Ayres to retain his name upon the Medical Register and this decision was undoubtedly arrived at on consideration of the facts of the case. These facts were fully set out in your report of the proceedings of the December session of the Council which was reported in THE LANCET of Dec. 6th, 1902, p. 1587. Shortly, they were these. A man named Baines who had been in the service of Mr. Ayres was discharged for drunkenness. Three days later Baines came to the surgery, being intoxicated, and demanded to know why he had been discharged. Mr. Ayres ejected him and shut the surgery door and returned to his consulting room. Then noticing Baines's hat on the table went out into the street and gave it to him. As he handed the hat to him Baines put up his hand and Mr Ayres, in warding off what he thought would be a blow, caused Baines to trip and fall. Baines was able to walk home and received no medical attendance for six days. Then the parish medical man was called in and Baines was removed to the hospital Death took place on the tenth day after the fall. At the post-mortem examination a fracture through the sphenoid bone was discovered, while the kidneys and the heart were found to be markedly diseased. At the trial the jury found the prisoner guilty, but they asked for a lenient sentence on the ground that there had been the greatest provocation. Mr. Ayres was, however, sentenced to four months' imprisonment, notwithstanding that he had already been ten weeks in prison.

I am anxious to appeal through your kindness in the columns of THE LANCET to the [illegible] profession on behalf of Mr. Ayres [illegible] he has five children and a wife [illegible] his earnings. His health has been broken by his sentence and he has had to give up all night work. I ask for a generous response to an appeal on behalf of a sorely tried professional brother Subscriptions will be received and acknowledged by Mr. O Morley Roberts, 67, Lord-street, Liverpool.

I am, Sirs, yours faithfully,
Liverpool, April 18th, 1903. A. AYRES.

FREE ANTITOXIN TO THE MEDICAL PROFESSION.

To the Editors of THE LANCET.

SIRS,—In a recent issue of THE LANCET I see the statement that at Hanley antitoxin has been lately supplied free of charge to medical practitioners for use as a prophylactic in cases of diphtheria and that this is probably the first instance of the sort in an English sanitary area. The States of Guernsey have, however, done the same for the last three years and in this respect are apparently pioneers in preventive medicine.—I am, Sirs, yours faithfully,

April 6th, 1903. M.O.H. (Guernsey).

---

[1] THE LANCET, April 18th, p. 1101.

DISCRETION IN PRESCRIBING.

To the Editors of THE LANCET.

SIRS,—The remarks of Dr. Nestor Tirard on hypnotics in THE LANCET of April 11th, p. 1022, excite an uneasy feeling whether the whole practice of prescribing does not need revision and reform. The general practitioner can get into a bad habit of hypnotising his patients with drugs, as this is easier and more often in demand than a carefully thought-out line of "masterly inactivity" or far-seeing *régime*, but he at least has it in his power to stay his hand if he makes his own medicines when the signals point to danger. The consultant, or he who does not dispense, on the other hand, once he has committed his directions to writing, which becomes the absolute property of the patient, ceases to be able to withdraw them from circulation or from repetition at the will of the patient. If we write a cheque we can "cross" it or make it "not negotiable," and almost everything that a lawyer commits to paper or parchment is safeguarded against abuse, and yet it is the medical man whose writing may spell, if abused, as it often is, either death or disaster beyond his ken. I do not know the precise legal aspect of a prescription, but why this *cacoethes scribendi* on the part of the prescriber? Why should he not make sure that his prescription shall be used only as he intends and by those only whom it is meant for? A general practitioner of my acquaintance who does not dispense secures this by sending all his prescriptions to a certain chemist with whom he has an arrangement that these should be copied out and retained, no charge being made to the patient by the chemist and no prescription ever repeated except by an order from the medical man. The plan works well for all concerned and is not very costly to the medical man and yet well worth the chemist's while. If necessary the chemist will send the medicine. But where ordinary prescribing is done, as by the consultant, why should he not initial and date his prescription and underneath add the letters s.q.n. ("sine quibus non [miscenda]")? If he wishes a certain number of doses to be taken before seeing the patient again he can order so many to be dispensed and the letters s.q.n. will warn the chemist to dispense no more until he is ordered by a fresh prescription or by re-dating or initialling the old one. An out-of-date prescription could not then be made up for anyone presenting it except, of course, at the chemist's own risk, and to do so would come to be regarded as "unprofessional" dispensing —in reality, illicit prescribing. If a consultant sees a patient sent to him by his medical attendant the prescription should be sent to the latter, not given recklessly to the patient himself. As illustrating the absurdity of present methods an old lady (now in her ninety-first year) was prescribed for some 20 years ago by an eminent man. A pill was ordered and a little whisky for her stomach's sake. The pill has been long discontinued, but the "stomachic" is still in use, and though the letter, not the spirit, has been departed from—for it now amounts to two gallons of whisky per month—steadily and regularly. The case illustrates the dictum that alcohol is "a *slow* poison," and any remonstrance is met by the answer that the prescriber was physician to the then Prime Minister. Verily "*verbum sapienti satest.*"—I am, Sirs, yours faithfully,

April 21st, 1903. CIRCUMSPICE.

A CORRECTION.

To the Editors of THE LANCET.

SIRS,—Dr. W. Mitchell of 21, Park-lane, Little Horton, Bradford, Yorks, has called my attention to the fact that the reference in my book entitled "A Third Pot-Pourri" to him as recommending vegetarianism to his patients is not warranted by facts and is calculated to injure his standing in his profession and affect his practice. I made the statement on the authority of another gentleman and did not, as I suppose I ought to have done, check the correctness of the information. I have already offered Dr. Mitchell my sincere apologies. Would you, Sirs, help me by inserting this letter to repair the error which my publishers will correct in all future copies? I am, Sirs, yours faithfully,

MARIA THERESA EARLE

Sloane-gardens, S.W., April 22nd, 1903.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Medical Charities.

HOSPITAL Saturday has been fixed for May 2nd, and the Red Cross Society, which is the workmen's branch of the Hospital Sunday and Saturday Fund, has issued an appeal to the public. Last year the expenses of the 20 medical charities aided by the Fund exceeded the income by £13,000, and the hope is expressed that this will be made good. The war is now happily over and there is nothing very special to divert public sympathy, but it will be a considerable step from £4171, last year's collection, to £13,000.

Coöperators and Convalescent Homes.

Some time ago a scheme for establishing convalescent homes by coöperators from societies in Lancashire, Yorkshire, and Cheshire was started. It was to be for the use of members of those societies in the north-western section. A home was to be established at Norbreck, near Blackpool, at a cost of £25,000. This scheme was perhaps too ambitious and it was opposed by some large societies in the section, so that it has been abandoned. A largely attended conference of coöperators met, however, on April 11th in Manchester to consider the matter. In the discussion the principle of the establishment of these homes was unanimously indorsed and ultimately a motion was carried declaring in favour of the establishment of two homes, one in Yorkshire and one in Lancashire, at a cost of from £10,000 to £12,000 each, and urging the committee to prosecute the work in the most vigorous manner possible. It may be hoped that this attempt will fare better than the first did and it is satisfactory to see that the principle of self-help is not yet lost among the better sort of the working-classes. In a paper read by one of the members it was maintained that "such homes should, in his opinion, be provided, not only because of the material benefits they conferred, but as an exemplification of the higher moral duties of coöperators in helping the poorer and weaker brethren and freeing them from the necessity of asking alms from the employer and rich classes who mainly supported existing convalescent homes." If such ideas were more widely spread there would be less hospital abuse than now prevails. But if the new scheme is to succeed it must be more warmly taken up by the societies than the abortive one was, in which the total amount of capital promised towards the £25,000 required was £2766.

The Small-pox Epidemic.

Small-pox is still prevalent in Lancashire. In Burnley 35 cases have occurred in the last seven days, and extension of the hospital accommodation is being hurriedly carried on, as it is at present quite inadequate. There have been eight cases at Heywood, chiefly among school children. Three public day schools have been closed. In Oldham no fewer than 10 cases have been reported from the workhouse since Friday last. Another case has been notified in Manchester from an entirely new district. Two more cases have occurred in Salford, bringing the total to 100. Stockport was said to be free yesterday for the first time in four months.

Midwives and Death Certificates.

The following case, as reported in one of the Manchester papers, indicates a danger to the public likely to increase rather than to diminish as the result of the recent Act affecting midwives which seems to invest them with a *quasi*-medical position. An inquest was held recently in Manchester by Mr. L. J. Aitken, the acting coroner, respecting the death of a baby accidentally suffocated in bed. The mother stated that six other of her children, though living for periods up to 10 hours, had been certified for burial by the midwife. Mr. Aitken, therefore, had the midwife in question before him on April 17th. The coroner's inspector told the court that when he visited the midwife's house to warn her to attend she told him that "her position entitled her to give a certificate that a child was stillborn, provided that it died within 24 hours after birth." As her view of the rights and privileges of midwives may be shared by others, perhaps it would be well for the societies which give diplomas to midwives to institute lectures, examinations, and diplomas or certificates in medical jurisprudence so that the *protégées* may be guarded against very serious errors. However, when before the coroner she said that that was not her meaning "What she did say, or should have said, was that she never gave any certificates for children born alive, but if a child did not live 24 hours she was always taught she had a right to give a certificate to the registrar" It would be interesting and instructive to know something more about her teachers in logic as well as jurisprudence The mother now also varied her statement, saying that she had had six children born alive A medical man's certificate was obtained for one and an inquest was held on another Mr Aitken then adjourned the inquiry, observing that there were still four children to be accounted for, and 'that he was determined to get to the bottom of the affair' In a certain section of the community very little value is attached to infant life and it is to be feared, to put it very mildly, that a good many midwives belong to that section Manchester, though not the worst does not hold a good position among the 76 great English towns as regards infant mortality, for, as Dr J Niven s last quarterly report tells us the deaths under one year were 181 per 1000 births during the quarter for the city, while in the old township of Manchester, which generally maintains a bad pre eminence, it was 198 per 1000 But if the death rate of this family represented the mortality of even the old *township, there would be a still more grievous loss of infant* life

Health Protection Budget

The estimates for the current year were presented yesterday at a meeting of the sanitary committee of the Manchester corporation The total expenditure anticipated is £84 283 The nuisance department costs £17,869, unhealthy dwellings £22 209, hospitals and infectious diseases, £43 023 Sale of Food and Drugs Act and Canal Boats Act, £1182 Last year however, the sum of £4312 of the estimate was not expended, so that when deducted from the current year s estimate the latter will be brought down to £79 971 The estimate of the cleansing committee for the year is £146 288 These are large sums, but Manchester is a great work a day city These committees do their work well and deserve the thanks of the community and if we count the cost of the safeguards of the public health it is worth while to try to picture the state of things if the work were not done.

The Scare as to the Pollution of Shell fish

To show the effect of the dread of typhoid fever from polluted shell fish, perhaps the following passage may be quoted from the report of the superintendent of the Lancashire and Western Sea Fisheries for the quarter ending March 31st last "Not only the weather but also the shell fish pollution scare has adversely affected the mussel fishery At Conway the demand fell off very considerably and many of the mussel gatherers took to line fishing for codling Mr Jones fishery officer, Carnarvon division, reports that the weight of mussels sent off by rail fell off as much as 50 tons per month as compared with the corresponding period of last year

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

Llandaff and Dinas Powis Health Report

THE voluntary notification of cases of pulmonary tuberculosis has been in force in the Llandaff and Dinas Powis district for nearly two years but the medical officer of health of the district (Dr R Prichard) in his recently issued report states that the system is practically a dead letter, as he only received one certificate during 1902 although there were 16 deaths registered as due to the disease The medical practitioners of the district decline to notify unless the disease is included in the list of those compulsorily notifiable under the Infectious Diseases (Notification) Act In his remarks upon the treatment of patients suffering from pulmonary tuberculosis Dr Prichard says that there appears to be little prospect of a sanatorium being provided in the neighbourhood of Cardiff at an early date for the isolation and treatment of the poorer class of cases, but that as tuberculosis is an infectious disease the proper authorities who should deal with it are those who are empowered to build hospitals under Section 131 of the Public Health Act, 1875 It is of interest to record the fact that Dr Prichard, who has hitherto been subject to re election as medical officer of health every three years, has now on the suggestion of the Local Government Board been appointed permanently

Death of Dr James Mathias Phillips

Through the death on April 14th of Dr James Mathias Phillips the town of Cardigan has lost not only its oldest practitioner but also one of the most prominent and public-spirited of its inhabitants Dr Phillips was born in 1838 and received his medical education at the Middlesex Hospital and the University of Aberdeen, becoming M R C S Eng in 1861 and graduating as M D in 1867 He began to practise in Cardigan in 1873, prior to which year he was surgeon to the Morfa collieries and to the Port Talbot tinworks For many years he was Poor-law medical officer and public vaccinator to the Cardigan union and was at one time surgeon to the Royal Naval Reserve His professional work did not prevent his taking part in the public life of the town, of which he was at one time the mayor, he was also on the commission of the peace for both the county and borough The public funeral accorded him testified to the respect and esteem in which he was held by his fellow townsmen He is survived by his widow a daughter and a son who is the resident surgeon of the Kasr el Aini Hospital in Cairo

Appointment of County Medical Officer of Health for Gloucestershire

At the meeting of the Gloucestershire county council held on April 13th Dr J Middleton Martin was appointed medical officer of health of the county Dr Martin will retain his present position as medical officer of health of the Stroud urban and rural districts and will receive from the county council 50 guineas yearly for summarising the reports of the district medical officers and for reporting on the health of the county, he will also be paid a fee of two guineas for attending meetings of the council or its committees and of three guineas daily when he visits under the instruction of the council districts outside his own. The population of the administrative county at the last census was 331 516 an increase of 7536 persons over the previous census There are 13 urban (including one municipal borough) and 22 rural districts in the administrative county and there are 20 medical officers of health There was practically no opposition to Dr Martin's appointment, a motion to postpone consideration of the question which was proposed by one county councillor not even being seconded

The Causation of Typhoid Fever

At a meeting of the West of England and South Wales Branch of the Incorporated Society of Medical Officers of Health held at Stroud on April 16th Major Robert Caldwell R A M C introduced a discussion on the causation of typhoid fever apart from water supplies and instanced his experience while in charge of troops at Korosko, a small Arab settlement 800 miles south of Cairo The camp was in a high state of sanitary efficiency but no special precautions were taken with regard to the water supply and the troops were singularly free from sickness of any kind Six months later he was at Korosko again and found the tents had been almost entirely replaced by huts and that many comforts were now obtainable which *formerly* were unknown but typhoid fever and dysentery were rife the continual occupation of the ground in a district where vegetation was deficient most probably favouring the spread of the disease Major Caldwell's experience in South Africa strengthened his opinion that conditions other than water supply were considerable factors in the production of typhoid fever among the troops and he referred to instances in Natal where the disease followed the continual use of the same ground for camping purposes He thought it not improbable that a non pathogenic bacillus owing to the contamination of the soil might become virulent Although he considered it necessary to procure a supply of 'safe' water for troops on service he thought that disappointment would ensue if conditions other than the water supply were overlooked and among such conditions pollution of the soil should occupy a prominent place In the course of the discussion Dr D S Davies of Bristol said that he could quite believe that the typhoid bacillus might exist in a harmless form in virgin soil [illegible] unless the conditions described by Major [illegible] Newport [illegible] generally

Association of Public Vaccinators

At a meeting held recently at Weymouth under the presidency of Mr J R Philpots it was decided to inaugurate

REBOUND 8 APR 1972

a Dorset branch of the Association of Public Vaccinators. Mr. Philpots was elected chairman of the branch and Dr. Lawson was elected secretary.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Enteric Fever in Glasgow.

A REPORT has been presented to the health committee by the medical officer of health (Dr. A. K. Chalmers) submitting a report by Dr. F. Dittmar on the distribution of enteric fever in the eastern district of Glasgow from 1897 to 1901. Dr. Chalmers in his introductory report deals first with the increased death-rate from enteric fever during the period 1891–1900. This is shown by the following figures which give the average annual rate per million for the whole city for each quinquennium during 20 years: 1881–85, 325; 1886–90, 185; 1891–95, 198; and 1896–1900, 242. The higher death-rate in the latter periods, especially the last, was not due to the greater fatality in individual attacks but was associated, as is shown in the report, with the greater prevalence of the disease. It is many years, as Dr. Chalmers points out, since Buhl applied to enteric fever Pettenkofer's observations on the relationship between the level of the ground water and the incidence of cholera. In the present instance we have the suggestion that there has been some association between the increased prevalence of the disease and years of increased rainfall. Thus, while in the years 1891–96 the average annual fall was 36·1 inches, during 1897–1901 it was 41·8, and, further, the wettest years, 1897 and 1900, were each followed by one of exceptional prevalence of enteric fever. The prevalence follows rather than coincides with the rainfall in any given year, the prevalence being related not to the amount of rain which falls throughout that year but to the quantity which falls in the early months. Thus the increased rainfall during the years 1897–1901 arose almost wholly from an excess falling in the first half, but especially in the second quarter of each year, while the cases of enteric fever occurring in the third and fourth quarters formed 66 per cent. of the total yearly number, as compared with 60 per cent. for the same quarters of 1891–96, the earlier months of which were much drier. The relationship of the prevalence of the disease and rainfall, however, as is pointed out, is not a simple one and would appear to be influenced by prevailing temperature, especially in the second and third quarters. But temperature and rainfall are not direct causes and Dr. Dittmar undertook an investigation with the view of ascertaining what connexion might exist between cases of enteric fever which in point of residence had a local association. The eastern district of the city was chosen, partly for its considerable size in point of population and also because it afforded an opportunity of contrasting the behaviour of the diseases in houses supplied with water-closets with those where middens still existed. The following abstract from Dr. Chalmers's report will show some of the more important results of Dr. Dittmar's investigation. In his analysis the term "secondary infection" is restricted to cases occurring in the infected household within the accepted limit of the period of incubation, and he finds that the proportion of these is least in one-apartment houses. This, as he points out, is most obviously related to the almost uniform practice of removing cases in these circumstances to hospital. But leaving those which may be regarded as direct infections, he found that in 71 tenements in which the disease recurred after the period of incubation had passed the recurrence took place in 12 families living on the same floor as the formerly infected house and in 47 families living on different floors of these tenements. And in considering the incidence of these with reference to the methods of excrement disposal his inquiry repeats the experience which has directed the policy of the committee of health in this respect for years. Recrudescence of the disease occurred in 23 per cent. of the invaded tenements which were dependent on dry or conservancy methods of dealing with excreta, and in 6 per cent. only of those supplied with water-closets. Regarding the former class the policy is already formulated and only requires to be persistently followed. Every midden is a potential centre for the spread of enteric fever and the more recent knowledge that infection may be voided in the urine serves to emphasise the unsuitability of these structures for town populations. In the process of emptying it is impossible to avoid surface pollution, and disinfection of the surrounding area is rarely practicable. On the other hand, the association of a small proportion (6 per cent.) of recurrent cases with properly constructed water-closets suggests the lack of a right appreciation of the uses to which these fittings may be put and illustrations are still too frequent in many districts of their abuse. Apart from the repression of this habit the inquiry further points to an extended application of the processes of disinfection. A perusal of Dr. Dittmar's interesting report will supply all the details upon which these observations have been founded.

St. Mungo's College: Appointment of Professor of Midwifery.

Dr. Robert Jardine has been unanimously appointed by the governors of St. Mungo's College to the chair of midwifery. Dr. Jardine is a Doctor of Medicine of the University of Edinburgh, Member of the Royal College of Surgeons of England, Fellow of the Faculty of Physicians and Surgeons of Glasgow, and Fellow of the Royal Society of Edinburgh.

April 21st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Poor-law Medical Service.

THE Irish Medical Association has at last achieved a certain measure of success in its efforts to improve the wretched conditions under which the medical officers of dispensaries and union hospitals in Ireland perform their important duties. The newly elected and popular boards have not yet learned their responsibilities and are in frequent conflict with their medical officers. The guardians of Dundalk union advertised recently for a medical officer for Dundalk workhouse at a salary of £100. The Irish Medical Association had fixed £120 as the minimum salary. No applicants appeared for the post and a committee was appointed to reconsider the question. On that occasion the guardians were almost equally divided in their votes. A similar deadlock occurred some months ago at Carrickbyrne, when the two candidates for that dispensary refused to accept a less salary than £200. In last July the Edenderry board of guardians appealed against the decision of the county court judge on the question as to the amount that should be paid to a substitute or locum-tenent for his services. It appeared that by a resolution of the board of guardians it was decided to pay one week's leave at £3 3s., with permission to the medical officer to take a further three weeks' leave provided that he paid his substitute. Mr. Justice Madden, in referring to the portion of the resolution which provided that a dispensary medical officer could get only one week's leave on full pay said that it was "grossly unfair and entirely against the spirit of the Local Government Board's regulations." The latest important question between a medical officer and his board of guardians is now being tried in the *Nisi Prius* court, Dublin, before a special jury and with eminent members of the Irish Bar employed on both sides. In this case Mr. O'Shaughnessy, K.C., with whom was Mr. T. M. Healy, K.C., M.P., stated that the plaintiff, Mr. J. Patrick O'Riordan, dispensary medical officer, sued the guardians of Celbridge union in respect of salary which they had deducted and also in respect of the sanitary condition of the house in which they were by law enabled to compel him to live. After three days' hearing, when several important witnesses were examined—including Sir Gerald Drove, D.L., a former chairman of the Celbridge Union; Mr. D. Coady, consulting medical officer of health of Naas Union; and Sir Charles Cameron, superintendent medical officer of health of Dublin, &c., the jury found for the plaintiff, Mr. O'Riordan, £5 damages in respect of the condition of his house and £56 5s. in respect of the deductions from his salary as rent for the time that he was not in occupation of the house.

Ulster Hospital for Women and Children.

At the annual meeting of the friends of the Ulster Hospital for Women and Children, held on April 7th, it was reported that during 1902 231 cases were admitted into the children's wards and 1682 were seen in the extern department, while in the women's department there were 84 intern and 313 extern cases. The maternity nurse attended 151 cases. The total number of cases to which the hospital afforded relief was 2466. The hospital is in debt to the extent of £1900.

The New Royal Victoria Hospital, Belfast.

A great public meeting, promoted for the purpose of enlisting active sympathy in the adequate endowment and maintenance of the new Royal Victoria Hospital (which will be opened during the summer), took place on April 20th in the great Ulster Hall, Belfast. Mrs. W. J. Pirrie (during whose year of office as Lady Mayoress the idea of founding a hospital to commemorate the late Queen's Jubilee was started) presided, and there was an immense audience crowding all parts of the building and consisting of the leading citizens and of representatives of the commercial, professional, and industrial classes. Among the speakers were Mrs. Pirrie, the Marquis of Londonderry, K.G., Mr. G. Wolff, M.P., the Right Hon. T. Sinclair, D.L., the Lord Mayor, and the High Sheriff of the city of Belfast, representatives of the various churches and of the working classes, while the medical and surgical staff of the hospital selected as their speakers Dr. J. W. Browne and Professor J. W. Byers. Mr. A. M'Dowell, clerk of the peace for the city of Belfast, acted as honorary secretary of the meeting, and to him largely is due its very great success. The feeling of the meeting in reference to the support of the new hospital was in favour of making an increased effort to meet the additional expenditure, while all idea of putting the scheme on the city rates was scouted by those present. Mrs. Pirrie, before the vast audience separated, was able to announce that with the additional subscriptions she had lately received the total amount of the building and endowment fund of the new hospital was £139,249 3*s.* 4*d.* and it was expected that large additions would be made. From a medical point of view the new hospital will in its architectural arrangements be much in advance of, and superior to, any of its size in the United Kingdom, while, as pointed out by several of the speakers, it will be a very great gain as a factor in the Belfast Medical School. The very greatest credit is due to the Right Hon. W. J. Pirrie and Mrs. Pirrie for the splendid way in which they have managed to bring to such a successful issue this great scheme to commemorate the late Queen Victoria's glorious reign.

April 21st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Political Opinions of the Hospital Medical Staffs.

THE medical men attached to the Paris hospitals are greatly excited by a new move on the part of the administration. The youngest—that is to say, the most recently appointed—members of the medical staff have had to appear before the mayors of their respective *arrondissements*, there to answer questions concerning their political opinions and as to the schools to which they send their children. Never before have any such measures been carried out and the medical men consider that they are quite beyond the power of the administration. When, as is the case with these medical men, from 10 to 15 years have been spent in education and a severe examination has been passed it is hard that the confirmation of the appointment should depend upon the results of an inquiry into the political opinions of the nominal holder of the post. On all sides protestations are heard from those who consider that the medical men who care for the sick should be free to do their work and to think as they like in so far as their private life is concerned.

Sterilised Milk in the Treatment of Infantile Atrophy.

At the meeting of the Hospitals Medical Society held on April 3rd M. Variot pointed out the excellent results obtained by feeding young children upon milk sterilised under pressure at a temperature of 108° C. M. Variot gave as an example the case of an infant who when six months of age weighed onl [illegible] suffering from atrophy. [illegible] sed under pressure at a te [illegible] later the child weighed eigh [illegible] walk, and showed no signs of [illegible] in a period of eight y [illegible] of milk sterilised in [illegible] on 1500 children, and in no one of these was there any sign of scurvy.

Magnificent Legacy to the Assistance Publique.

The Assistance Publique has just received a generous legacy from M. Bigottini, a rich inhabitant of Auteuil. He left the Assistance his whole fortune except 200,000 francs which has been allocated towards the support of an asylum for persons suffering from tuberculosis.

The Treatment of Tetanus.

M. Bazy, who had been appointed by the Society of Surgery to report upon a case of tetanus under the care of M. Mauclaire, read his report before the society at the meeting held on April 8th. The patient was a man who 15 days after having been bitten by a horse had had his arm amputated at the shoulder-joint. Two preventive injections of anti-tetanic serum had been given on the day after the bite and one on the next day. [illegible] of tetanus. [illegible] by repeated [illegible] of serum wh [illegible] twenty-fifth day after the tetanic symptoms had appeared he was quite well. M Mauclaire has given details of 12 cases of tetanus in which there were 10 deaths and two recoveries. Arguing from the treatment applied in the two last cases M. Mauclaire considers that preventive injections attenuate the poison and that bleeding also plays a part in the cure.

April 21st.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Public Medical Services in Berlin.

A MEETING of medical men was recently held in Berlin at the instance of the "Free-choice" Society for the purpose of considering the various systems at present followed in the public medical services of the city, with a view to make suggestions for their improvement. In the result a petition containing recommendations on the following points was drawn up for transmission to the Berlin municipal authorities. 1. The arrangements for the treatment of patients under the poor-law require alteration. At present each poor-law district has one medical officer who is appointed by the municipal council and receives a fixed salary, but it is now suggested that the "free-choice" system which was extensively applied in club practice should be made the rule in poor-law practice also. The attention of the authorities was at the same time drawn to the fact that the late Professor Virchow had advocated this method as long ago as 1848 and that some of the smaller towns in Germany had already adopted the "free-choice" system for their poor. 2. Another recommendation referred to the medical and surgical staff of the municipal hospitals. The three great municipal hospitals—the Urban Hospital, the Moabit Hospital, and the Friedrichshain Hospital—contain respectively 631, 993, and 753 beds and are usually overcrowded almost all the year round. At the present time only two chief physicians and one chief surgeon are appointed for each of these hospitals, but there are, of course, a number of [illegible] surgeons. The consequence [illegible] with his assistants has to [illegible], a number which is evidently too great, and the petitioners therefore recommend that additional chief medical officers should be appointed to these three hospitals so that the number of patients treated by each of them should not exceed 150. Provision ought also to be made for special departments, which as yet have been formed only in the Royal Charité Hospital and in the university clinics but not in the municipal hospitals. 3 The next recommendation related to medical supervision of the municipal schools. In German towns and cities other than [illegible] the hygiene of schools an [illegible] for a long time been de [illegible] medical me [illegible] until three [illegible] as an expe [illegible] whom atten [illegible] to have passed the experimental stage and the system is to be extended to the whole city; 30 medical officers will be appointed at salaries of 2000 marks (£100) and each of them will attend seven schools. The duties of a school medical officer are somewhat heavy, including the supervision of the hygienic arrangements of the premises, careful examination of new pupils, selection of weak-minded and defective children for instruction in special classes, the making of the arrangements which become necessary in time of epidemics, and last, but not least, the preparation of reports for the school board. A medical officer who is anxious to do his duty must therefore either give nearly all his time to the school work (which is practically impossible on a salary of £100 a year) or else the amount of the work must be lessened. The petition of the "Free-choice" Society proposed that every girls' and boys' school should have its own medical officer and that the number of medical officers appointed should be 200 in place of 30. 4. The next paragraph of the petition recommends that the municipal authorities should appoint a chief medical officer as head of the entire medical service of the city of Berlin. He ought to have an adequate salary and it would be his duty in conjunction with his subordinates to advise the municipal council on questions concerning hygiene, water-supply, the construction and management of hospitals, infirmaries, and lunatic asylums, and other matters of a like kind. At present there is no medical man having responsibility in these particulars, the work being undertaken partly by persons possessed of no medical knowledge and partly by town councillors who happen to be medical men although they have not been elected to the council in virtue of their professional attainments. The majority of German towns have their recognised advisers in matters of public health and are provided with laboratories where bacteriological and chemical investigations can be carried on, but in the metropolis these conditions do not exist and when such investigations become necessary it is only by the courtesy of the heads of the university laboratories that they are made. 5. The concluding paragraph deals with the method of applying for appointments in the Berlin municipal service. After making an allusion to some unfortunate events which have taken place on the occasion of appointments becoming vacant in the municipal hospitals the petition recommends that canvassing should be strictly prohibited and that vacancies should be publicly advertised. Finally, the petitioners state that in the task which they have set themselves they have been actuated solely by regard for the interests of public health and not by any undue sympathy for the medical profession.

The Antipyretic Treatment of Typhoid Fever.

Professor Valentini, chief physician of the Deaconesses Hospital at Danzig, in West Prussia, has published in the *Deutsche Medicinische Wochenschrift* a very favourable account of the results which he has obtained in the treatment of typhoid fever with pyramidon. He points out that the treatment by means of cold baths, which has for many years been used almost everywhere, requires a fully trained nursing staff and therefore is not always available in private practice. Cold bathing, moreover, is not suitable for indiscriminate application and has been known to produce collapse. The internal administration of pyramidon yields equally good results with much less fatigue and discomfort to the patient and much less work for the attendants. The temperature becomes normal, the frequency of the pulse decreases, cerebral symptoms such as delirium disappear, and a great change for the better in the patient's condition is apparent in from 24 to 36 hours. The dose of pyramidon is 0·2 gramme (three grains) in mild cases and 0·3 or 0·4 gramme in severe ones. These doses should be given regularly every two hours day and night until the temperature becomes normal. In mild cases the cerebral symptoms usually disappear very soon and the patient's mind becomes quite clear after 24 hours' treatment; in severe cases attended with unconsciousness the improvement in the cerebral symptoms does not show itself until after the lapse of about 48 hours, when the patients become able to answer questions and to drink without assistance; the effect on the pulse was, of course, less marked than in the mild cases. The temperature became normal in every instance after a sufficiency of the remedy had been given. The treatment ought not to be commenced until the diagnosis is certain and must then be continued for three or four weeks; after this it may be stopped and the effect carefully watched so that it may be resumed if there is any recurrence of pyrexia. Dr. Valentini treated 19 cases by this method with two deaths, one of which was due to pyæmia and the other to cardiac debility. No ill-effects or undesirable sequelæ were observed. Pyramidon does not seem to have a specific influence on typhoid fever. Its action is palliative and it does not shorten the course of the disease.

April 20th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Dissensions in the United States Red Cross Society.

As a result of public criticisms of Miss Clara Barton's management of the United States Red Cross Society the official organisation has suspended from active membership the more prominent of the malcontents. These include General John M. Wilson, U.S.A., retired, who last year was vice-president of the society; ex-Secretary of State John W. Foster; ex-Secretary of the Navy Hilary A. Herbert; Rear-Admirals Van Reypen and Ramsay, U.S.A., retired; and Mrs. Anna Roosevelt Cowles, sister of President Roosevelt. All the above-mentioned are Washington members of the Red Cross who presented a memorial to Congress protesting against the present methods of managing the Red Cross Society. The signers of the memorial asserted that the affairs of the society by recently adopted by-laws were placed wholly in the hands of its President, Miss Clara Barton, and the object of the memorial was to endeavour to bring about a reorganisation of the society through the retirement of Miss Barton from the active presidency to the honorary presidency on an annuity.

Political Control of New York State Charitable Institutions.

The Governor of New York State has caused to be passed laws which will oust the Charity Organisation from any control or supervision over the various State institutions. The new method of management is termed a centralisation scheme, under which the expenditure of about $2,500,000 (£500,000) annually granted for supplies to State hospitals, charitable and reformatory institutions, and prisons will be in the hands of politicians. The medical journals of the State have been unanimous in condemning the scheme.

Hydrophobia in Chicago.

There has been a considerable amount of hydrophobia in some American cities of late. New York city has had several cases and there have been more in Chicago. Dr. Arthur Dean Bevan recently read a paper before the members of the Chicago Hospital Society entitled "Hydrophobia Prevalent in Chicago: Measures for Prevention." In the course of his address Dr. Bevan said that the report of the local Pasteur Institute showed a total of 1838 persons treated in the past 12 years. Of these, only seven died, an admittedly brilliant result. He, however, was somewhat sceptical as to the good effects of the treatment, owing to the difficulty of establishing the fact that the animal producing the bite was mad and because of the impossibility of determining the actual proportion of cases developing from the bites of infected animals. Nevertheless, he was convinced that the Chicago dog-muzzling law was inadequate. The speaker went on to say that there have been 91 known deaths from rabies in Chicago since 1891, although he was not satisfied that these figures represented the full mortality from that cause. He designated the city dog-law as stupidly inefficient, inasmuch as it was inactive between Nov. 1st and April 1st, and quoted statistics demonstrating the fallacy of the belief that dogs do not go mad in winter.

New York City Hospital Saturday and Sunday Fund.

The Hospital Saturday and Sunday Fund of New York city amounted this year to $68,000 (£13,600) which the distributing committee has divided among 37 hospitals in sums varying from $6800 (£1360) to $250 (£50).

April 15th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Milk Supervision in Victoria.

THE Board of Public Health in Victoria has for some time been considering, and has now drafted, a Bill for the supervision of the milk-supply. The chairman, Dr. D. A. Gresswell, has outlined the main provisions of the Bill which contains at least three or four requirements which have not hitherto been matters of legislation. Power is given to make regulations concerning a large variety of subjects, dealing with the milker, with the cow to be milked, and with a variety of details relating to the dairy farm. Dairymen themselves are to furnish the municipal councils at regular intervals with certificates from duly qualified veterinary surgeons as to the condition of their cattle—an innovation which will reduce vastly the quantity of work required from the councils' veterinary experts. The Bill also gives power to councils and to the Board of Health absolutely to forbid the use of cows for milking purposes for human consumption whenever, in the opinion of a council or of the board, such cows are likely to yield unwholesome milk. The board or the council is the final arbiter in deciding whether or not the milk of a cow is wholesome. The Bill also gives the councils power to forbid the use of cows for furnishing milk for human consumption in cases where an outbreak of disease has been traced to their satisfaction to a particular cow or cows. A comprehensive clause prohibits the selling, under the name of "milk" or "entire milk" or other name indicative of unchanged milk, of any article of diet which is not absolutely the unchanged product of the udder of the cow. There is, however, a modifying clause allowing the addition of ingredients by order in council, on the recommendation of the Board of Health. If the board said that a certain chemical substance might be added as not being unwholesome, then there would be power, under the Act, to have it gazetted by an order in council, and such addition would then be legal.

Hospital Affairs.

The annual meeting of the Sydney Hospital was held on Feb. 3rd, the Governor of New South Wales presiding. The annual report stated that the past year had been one of marked activity and that the hospital was in a condition of efficiency it had never before attained. The financial position had been well maintained and the subscriptions showed a substantial increase. The following statistics were submitted: Patients remaining in hospital on Dec. 31st, 1901, 304; patients admitted during 1902, 4201; total under treatment, 4505; discharged cured, 2628; relieved, 933; unrelieved, 167; died, 453; remaining in hospital on Dec. 31st, 1902, 315; percentage of mortality on cases treated, 10; average number of admissions per week, 80; largest number admitted in one week, 103; smallest number admitted in one week, 63; average number of beds occupied, 298; largest number of beds occupied, 324; smallest number of patients, 255 (during repairs to the Moorcliff branch); average duration of stay in days, 27; number of accidents and urgent cases admitted without recommendations, 1670; number of patients admitted on Government orders, 1915; number of patients admitted on subscribers' orders, 87; number of patients admitted who contributed to their maintenance, 529. Of the 453 deaths 128 patients died within 24 hours of admission. The number of operations performed during the year was: At the main hospital, 2361; at the Moorcliff branch, 447: dental operations requiring anæsthetics, 146; total, 2954 The statistics of the out-patients' department are: medical department, 7641 new cases, 31,202 attendances; surgical department, 3914 new cases, 13,569 attendances: eye department, 1636 new cases, 7907 attendances; ear, nose, and throat department, 1516 new cases, 7438 attendances; skin department, 711 new cases, 4019 attenda[illegible] 979 new cases, 5444 attenda[illegible]w cases, 314 attendances. [illegible] Total: 16,711 new cases, 69,893 attendances. Casualty department, 10,176 new cases, 20,127 attendances. The balance sheet showed that compared with the previous year the expenditure had been increased by £1040, and compared with 1900 by £2656. Subscriptions, compared with 1900, had increased by £936, and exceeded those for 1901 by £852, exclusive of £150 received from the *Children's* Industrial Exhibition. The additional contributions were attributed to special coronation donations. It [illegible] expense, owing to the dr[illegible] amount to nearly £2000. [illegible] during the past year and the carrying out of many repairs, however, a reasonable surplus would be carried forward. The maintenance per bed for the year had been £67 against £63 7*s*. 7*d*. for 1901. For the current 12 months the cost is estimated at £71 2*s*.—Dr. C. V. Bowker has resigned the position of medical superintendent of the Sydney Hospital. Dr. Maitland has been appointed surgeon, and Dr. H. S. Stacey assistant surgeon.—The annual meeting of the Balmain Hospital was held on Jan. 28th. The report showed that a great deal of work had been satisfactorily done and that there was a credit balance of £467. Mr. C. U. Carruthers moved that it was advisable that a resident medical officer should be appointed. He said that the growth of the hospital had been rapid and that it was impossible for a medical man who had private practice outside the hospital to give fair and prompt attention. The committee paid a non-resident medical officer £150 a year. A resident officer could be obtained for £120 a year and board and lodging. Mr. T. M. Harding seconded the motion. Dr. L. G. Davidson, the late paid medical officer (who recently resigned), said they could not get a competent resident medical officer at £120 a year and he was willing to continue in his position till his successor could be appointed. The motion was lost by a large majority.—A conference was held in Melbourne on Feb. 4th of representatives of the various hospitals in Victoria to consider the advisability of securing an amendment of the Hospitals Act. The conference was the outcome of a discussion of the by-laws of the Women's Hospital with regard to the election of the medical staff by the subscribers. Certain suggested amendments could not be carried out without an alteration of the Hospitals Act. It was argued that at present it is inadvisable to do anything in the direction of inducing the Government to amend the Charities Act, and the following amendment was carried:—

[illegible]

The committee of the Women's Hospital, Melbourne, is considering a proposal to provide accommodation for the reception of cases of puerperal septicæmia at an estimated cost of £400. Up to the present such cases have been rigorously excluded. The question was referred to the building committee as the estimate was considered too low.

March 10th.

Obituary.

FRANCESCO COLZI.

UNDER date, Florence, Palm Sunday, one of our Italian correspondents writes: Tuscany nay rather Italy—indeed, the healing art "ubique gentium"—are to-day lamenting the loss of one of the most brilliant and successful surgeons of his time. Francesco Colzi, after a heroic struggle of ten days' duration, succumbed on April 4th to the terrible gunshot wound received in circumstances already made known to the readers of THE LANCET.

For some 72 hours the skilful medication of the fractured arm and lacerated axilla seemed to justify the abstention from amputation—the course approved by the eminent consultant, Professor Bassini of Padua. Bulletins were issued night and morning to meet the solicitude of the sympathising public, from the King and Court of the Quirinal downwards, and the tenour of these, while not sanguine, could not be called discouraging. But by March 30th, when gangrenous points began to declare themselves, the thought of saving the arm had to give way to that of saving life itself, and after a long consultation, held before Professor Bassini could arrive from Padua, it was decided to perform the amputation which Professor Colzi had counselled from the first. At the professor's own request the operator was his old and favourite pupil and clinical assistant. [illegible] great skill to remove the arm [illegible] The operation, which w[illegible] the patient maintaining an impassive yet vigilant calm, was an admirable specimen of the surgeon's art and the subsequent medication, in which Dr. Stori was assisted by his colleagues Professor Burci and Professor Del Greco, seemed to give fresh assurance that the precious life might be preserved. The prognosis was further reinforced by the indomitable pluck, not to say vivacity, of the patient himself who, contemplating his lost arm, said: "E dopo? Che farò per occupare il tempo? Anderò a studiare chimica nel gabinetto del Professore Piccini." ("And after? What shall I do to employ the time? I'll go and study chemistry in Professor Piccini's laboratory.") But *Dis aliter visum.*

Just before the operation some liquid that had oozed from the wound had been analysed and the bacilli of tetanus were detected, although the patient manifested no tetanic symptoms. The appropriate serum was at once obtained from Milan and with Professor Colzi's consent was injected in very high doses. But the characteristic spasms did not fail to present themselves—even though the serum, still in the highest doses, was injected in the immediate neighbourhood of the wound. How had these bacilli been introduced? At the consultation it was left undetermined whether they had found their way in with the gunpowder, or the dust of the highway, or the shreds of clothing. Meanwhile the convulsive contractions, of the countenance first and then of other parts of the body, increased in intensity and frequency, the patient still maintaining perfect lucidity of mind and even discussing the phenomena as if he were lecturing in the pathological theatre. By this time the public anxiety, fed by the bulletins, had become as painful as it was universal, and among the innumerable callers at the hospital was His Royal Highness the Count of Turin, representing the solicitude of the Royal Family and Court. On April 3rd the tetanic convulsions involved the spina dorsalis and the lower extremities and at last the patient besought his colleagues to minimise his sufferings as far as they could. All hope of saving life was gone and after making sundry dispositions in presence of his immediate relatives (Professor Colzi was unmarried) he received the consolations of the Church from the Capuchin Padre Paolo attached *ad hoc* to the hospital. By 2 A.M. of April 4th he became delirious—the clinical staff assembled round his bed (Professor Grocco, Professor Banti, Professor Lustig, Professor Del Greco, Dr. Stori, Dr. Marchetti, Dr. Lenzi, and Dr. Berchielli) praying inwardly for the speedy advent of death as a relief to such agony. This did not come until 3 P.M., when a violent convulsive attack involved the heart and Francesco Colzi was no more.

The whole press, professional and lay, throughout Italy is unanimous in deploring his death in obituary notices more or less extended. From these I gather that he was born of a good family at Monsummano in Tuscany in 1855; that he was slow of development, having reached the age of nine years before he could read or write; that he made abnormally rapid progress at the University of Pisa and again at the Istituto di Studi Superiori at Florence; and that he graduated with great distinction in 1877 and thereafter made a tour of the principal cliniques of Europe as a post-graduate course. In 1879 he became assistant in surgery at the Hospital of the Santa Maria Nuova, and from 1883 to 1886 filled the post of assistant dissector in the Cabinet of Pathological Anatomy. In the latter year the illustrious Dr. Corradi, professor of surgery in the Florentine School, made him his assistant, a post which he held till 1892, after which he was elected extraordinary professor of clinical surgery in the University of Modena. Before the year was out he returned to Florence and finally succeeded Professor Corradi himself, first in 1897 as extraordinary and then in 1902 as ordinary professor of clinical surgery. Some notion of his activity and success in his chosen branch of the profession may be gathered from his "Contributo di Clinica Operativa," published 12 years ago, in which he tabulates and describes 843 operations performed by himself between 1886 and 1891. Of these 801 were successful; six were relieved or in course of cure when the volume was published; four were, on its publication, in the same condition or showing symptoms of relapse, necessitating supplementary interference; and of the 32 persons who died the majority succumbed to ailments other than those which had required his intervention. Extirpation of the larynx was one of his most brilliant successes, but the radical cure of hernia on the lines of Bassini's method brought him most into notice. There were 20 sufferers from this malady, in conditions more or less urgent, awaiting him on the day after the casualty that laid him low. For his contributions to the literature of this subject the reader may be referred to the professional journals of Italy; the leading Tuscan newspaper, the *Nazione* of Florence, fills half a column of its space in enumerating their titles alone.

WILLIAM BERRY KELLOCK, M.D. ST. AND., F.R.C.S. ENG., L.S.A.

By the death of Dr. W. B. Kellock at the ripe age of 82 years the north of London has lost one of its oldest and most respected practitioners. Coming from a family which included many generations of medical men he was apprenticed to his father in his native town of Totnes, Devonshire, received his medical education at Guy's Hospital, became a Member of the Royal College of Surgeons of England in 1843, a Licentiate of the Society of Apothecaries, and doctor of medicine (St. Andrews) in the following year, and in 1878 was elected a Fellow of the Royal College of Surgeons of England. Dr. Kellock was for a time resident medical officer at the Stamford-hill and Stoke Newington Dispensary, in which institution he always took a lively interest and with which he was connected as surgeon and consulting surgeon throughout the remainder of his life. He was one of the oldest Fellows of the Medical Society of London and a Fellow of the Linnæan and Royal Horticultural Societies. Throughout an active practice extending over nearly 50 years his wide knowledge of his profession, his handsome, commanding presence, and his extreme kindliness of manner made him trusted and respected by several generations of patients; jealous to a degree of the integrity of his profession and its traditions he possessed an absolutely unbiased mind, always appreciative of real advances in modern medicine and surgery. Although advancing years made him relinquish active practice some 12 years ago his advice and help continued frequently to be sought by former patients and they are not a few who will grieve at the passing away of one of the wisest and kindest of friends and one of the most upright of men. Dr. Kellock left no family and his body was buried at Totnes with that of his wife who died in 1901.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the second examination of the Board at the April quarterly meeting of the examiners in Anatomy and Physiology:—

Leonard Ernest Acomb, Middlesex Hospital; Arthur Lionel Baly, B.A. Camb., Cambridge University and Middlesex Hospital; Frank Cyril Harvie Bennett, St. Mary's Hospital; Parvatiprasad Vishvanath Bhatt, St. Bartholomew's Hospital; William Thomas Briscoe, B.A. Camb., Cambridge University; Cuthbert Garrard Browne, Westminster Hospital; Frederick Henry Montagu Chapman, St. George's Hospital; William Winsland Douglas Chilcott, Charing Cross Hospital; Emil Christofferson, University College, Bristol; John Clarke, University College, Sheffield; George Cockcroft, Guy's Hospital; Herbert Alfred de Pinna, Toronto University and Middlesex Hospital; Gurth Eager, King's College, London; Kenneth Edward Eckenstein, University College, Liverpool; Thomas Llewellyn Evans, University College, Cardiff; Arthur Roland Fisher, Yorkshire College, Leeds, and King's College, London; Claude Francis Fothergill, B.A. Camb., Cambridge University and Guy's Hospital; Howard Græme Gibson, Guy's Hospital; Robert Gray Gillies, Middlesex Hospital; Carleton Wyndham Gittens, University College, London; Morris Grundy, Cambridge University and King's College, London; Horace Gooch and Eric Henry Rhys Harries, London Hospital; Thomas Reginald Harvey, Guy's Hospital; Robert Francis Hebbert, St. Thomas's Hospital; Montague Leonard Hine, Middlesex Hospital; George Montague William Hodges, University College, London; Frederick William Hobbs and Walter Leopold Holyoak, St. Mary's Hospital; Cyril Bertram Hutchison, London Hospital; Thomas Jones Jenkins, University College, Cardiff; Valentine Goode Johnson, St. Mary's Hospital; Harold Emlyn Jones, London Hospital; Henry John Sulling Kimbell, St. Bartholomew's Hospital; Henry Andrew Lash, St. Mary's Hospital; Thomas Bramley Layton, Guy's Hospital; Robert Lecky, University College, Bristol; David Thomas Lewis, University College, Cardiff, and Middlesex Hospital; Herbert Bowen Maxwell, London Hospital; Patrick Francis McEvedy, John Harry Mayston, and Gerald Hamilton Morris, Guy's Hospital; Albert Clifford Morson, Middlesex Hospital; Hubert Cowell Mulkern, St Mary's Hospital; Charles Max Page, St. Thomas's Hospital; Hubert Arnold Pallant, Guy's Hospital; Jeffery Wimperis Parker and Alan Randle, University College, London; Frederic Eustace Leigh Phillips and Arthur Haig Pollard, London Hospital; Edward Ebenezer Rendle, Guy's Hospital; Cecil Frank Rumsey, Charing Cross Hospital; William Octavius Sankey, St. Thomas's Hospital; Frederick Smith, University College, Sheffield; Leslie Ernest Maule Smith, Charing Cross Hospital; Reginald Thane Taylor, London Hospital; Edmund James Fairfield Thomas, University College, Bristol; Charles Henry Burton Thompson, Middlesex Hospital; George Gilbert Timpson and Horace Ernest Humphrey Tracey, Guy's Hospital; William Fentham Todd, Lon [illegible] Frederick Boileau Treves, B.A. Camb., Cambridge [illegible] r Walker, Yorkshire College, Leeds; Cu [illegible] University College, London; John Charles [illegible] Hospital; and Arthur Zorab, Guy's Hospital.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—T. W. S. Hills (Section I.), Cambridge and St. Mary's Hospital; D. J. Lewis (Sections I. and II.), London Hospital; W. S. Lewis (Section I.), Birmingham; E. H. Noney, (Section II.), Calcutta and Westminster Hospital; J. A. Renshaw (Section I.), Manchester; and C. C. Rushton (Sections I. and II.), University College Hospital.

Medicine.—H. J. Aldous (Sections I. and II.), King's College Hospital; F. G. H. Cooke (Section II.), University College Hospital;

J. W. [illegible]

[illegible] (Sections I. and II.), London Hospital.

Forensic Medicine.—J. F. Ellis, St. George's H[illegible]

[illegible] Hospital; J. A. Renshaw, Manchester; and J. P. B. Snell, Middlesex Hospital.

[illegible] dates, C. O. [illegible]oney,

UNIVERSITY OF DURHAM.—At the examination for the degree of Bachelor in Medicine, held in April, the following candidates satisfied the examiners:—

FIRST EXAMINATION.

1. [illegible]

2. [illegible]

3. [illegible]

4. [illegible] Newcastle-upon-Tyne.

[illegible]

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the April sittings of the Scottish Conjoint Medical Board held in Glasgow the following candidates passed the respective examinations:—

F[illegible]*urse*).—Laura Gertrude Powell, [illegible] Ernest Barrett, Leeds; Jeremiah [illegible] Hume Patterson, Langside; John Arthur Smith, Glasgow; Thomas Forrest M. Leishman, [illegible]

[illegible] Ashurst, Govan (with [illegible] Percival Henderson, [illegible] (with distinction); [illegible]deric James Breakell, [illegible]

S[illegible] [illegible]hn Stothart Farries, Leeds [illegible]

[illegible] Kennedy Joseph O'Brien, Galway.

UNIVERSITY OF GLASGOW.—The following have passed the first professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (B., Botany; Z., Zoology; P., Physics; and C., Chemistry):—

John Andrew Aitken (C.), James Montgomery Anderson (P.), John Anderson, M.A. (B., Z.), Thomas M'Call Anderson (Z.), Andrew Hamilton Arnott (C.), David Arthur (B., Z.*), John Atkinson (Z.), Edgar Barnes (Z.*), Herbert Bertram (Z.,* C.), John Henry Bisset (B., Z., P. [illegible] M.A. (Z., C.), Murdo Buchanan [illegible] James Cairns (Z.,* C.), Thomas H[illegible]ew Ignatius Thornton Cassidy (Z[illegible] (B.), Alexander Beck Cluckie (P.), Alexander Johnston Couper (B., P.), James Robert Craig (Z.), [illegible] Dick (B.), John [illegible] (B.), James Richa[illegible] Donald Duncan ([illegible] Bowman [illegible]ck, M.A. [illegible]), James M'Ilroy [illegible] David John Williams (B.), Frank Ritchie Wilson (Z.,* C.), Hugh Mundle Wilson (Z.), William Mitchell Turner Wilson (B., P.), Garabed Yeghis Yardumian (Z., C.), and Matthew Young (Z.,* C.).

Women.—Annie M'Crorie (P., C.), Janet Annie Macvea (C.), and Jane Isabel Robertson (P., C.).

The following have passed the second professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (A., Anatomy; P., *Physiology*; and M., Materia Medica and Therapeutics):—

Scott Campbell Adam (M.), George Allison Allan (A., P.*), William Allison (A., P., M.), Andrew Henderson Baird, B.A. (A., P.), [illegible]er (A.), George Duncan Morrison [illegible]), Thomas Murdoch Campbell, [illegible] Chislett (A.), Thomas Goodall Copestake (P.), Weir Burns Cunningham (M.), Robert Wilson Dale, M.A. (A.,* P., M.), Robert Scott Dewar, M.A. (A., P., M.), Allan Campbell Douglas (A., P.), Walter Duffy, M.A. (A., P., M.), John Shaw Dunn, M.A. (A.,* P.*), Eric John Dyke (A., P.), Hamilton William Dyke (A., P.), James Fairley (A., P., M.), Harry Prescot Fairlie (A., P., M.), Alexander Burns Ferguson (A., P., M.), Edward John Fitzgerald (M.), William Gilchrist (P., M.), Joseph Glaister (M.), Alexander *Graham*, B.Sc. (A., P.), William Grier (A., P.), Frank Hauxwell (A.), James Waugh Hay (A., M.), Robert M'Cowan Hill (P., M.), [illegible]ald, M.A. [illegible] Macintyre [illegible]cleod (P.), [illegible] Drummond [illegible] (A.), Peter Maguire (A., P., M.), James Marshall (A.), William Blair Morton Martin (M.*), Robert May (P.), Henry Joseph Milligan (A., P., M.), David Robertson Mitchell (A., P., M.), William Struthers Moore (A., P., M.), Gavin Denholme Muir (A., M.), Frank Anderson Murray (M.), Patrick Joseph O'Hare (P., M.), Henry Sherwood Ranken (A., P.,* M.), Cunison Deans Rankin (A., P., M.), Thomas Thomson Rankin (A., P[illegible] M.), [illegible] Capp[illegible] Sans[illegible] Hern[illegible] Alex[illegible]

[illegible] Annie Thomson Clark, [illegible]abeth Maud M'Vail, [illegible] Jessie Deane Rankin.

M.A. (A., P., M.), Mary Spence (A., P., M.), and Annie May Yates (A.).

The following have passed the third professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B) in the subjects indicated (P., Pathology; and M., Medical Jurisprudence and Public Health):—

Archibald Craig Amy (P., M.), Henry Graeme Anderson (P.), James Richard Sunner Anderson (M.), John William Arthur (M.), David Blackley (P., M.), Forrest Brechin (P., M.), Charles Brown (P., M.), George Yuille Caldwell (P., M.), Peter Carrick, M.A. (P., M.), Robert Buchanan Carslaw, M.A. (P.*), Robert Peploe Cartwright (P.), James Alexander Cowie, B.A., B.Sc. (P., M.), David William Davidson (M.), Thomas Thornton Macklin Dishington (P.), Hugh M'Millan Donaldson (M.), Charles Milligan Drew, M.A. (P., M.), Hugh Harvey Fulton (P.*), George Garry (P.), James Gemmell (M.), William Harold Gillatt (P., M.), William Macmillan Gilmour (P., M.), David Livingstone Graham (P., M.), John Graham (P., M.), George Munn Gray (P.*), Louis Leisler Greig (P., M.) John Cochrane Henderson (P., M.), Alexander Jamieson (P.), Robert Dallas Kennedy (P., M.), John Kerr (M.), William Henry Kirk (P., M.), Robert Thomson Leiper (P., M.), William Jamieson Logie (P., M.), Thomas Symington Macaulay (P., M.), John Duncan M'Callum, M.A. (P., M.); Donald Carmichael M'Cormick (P.), Neil M'Dougall (M.), James Boston M'Ewan (P., M.), Tom Duncan M'Ewan (P [illegible] M'Farlane (P.*), Robert Maxwell [illegible] M'Guire (P., M.), James M'Hou [illegible] Ronald Mackinnon (P.), David [illegible] (P., M.), Norman Alexander Macleod (M.), Andrew Brown M'Pherson (P., M.), Andrew Meek (P., M.), Peter Millar (P., M.), John Muir (P., M.), Macdonald Munro (P., M.), George Clement-Nielson (P., M.), Thomas Orr (P.), Howard Henderson Patrick (P.), John Clegg Pickup (P., M.), Alexander MacMillan Pollock (M.), Andrew Maclean Pollock (P.), James Porter (P.), William Murdoch Rae (M.), Donald Ronald Reid (P.,* M.), Daniel Stevenson Richmond (M.), Berkeley Hope Robertson, M.A., B.Sc. (P., M.), Robert Thin Craig Robertson (P., M.), George Goldie Smith, B.Sc. (P.), John Stewart (P., M.), [illegible] (P., M.), William Craig Stewart (P., M [illegible] (P., M.), William Templeton (P., M.), [illegible] (P.), William Young Turner, M.A. (P., M.), Hugh Fleming Warwick (P.), Robert Watson (P.), Archibald Crombie West (P., M.), Archibald Simpson Wilson (P., M.), David Watson Wilson (P.), George Wilson (M.), Robert M'Nair Wilson (P., M.), and Watson Young (P.)

Women.—Annie Agnes Baird, M.A. (P., M.); Annie M'Caig Black (P., M.), Roberta Campbell (P.), Ethel Lily Chapman (P.), Jane Hamilton M'Ilroy M.A., B.Sc. (P., M.); Jane Stark M'Lauchlan (P., M.), Charlotte Reid Park (P.), Jane Reid Shaw (M.), Lily Smellie (P., M.), and Elizabeth Taylor Talbert (P., M.).

* Passed with distinction in the subjects indicated.

Mr. Ernest Milton Watkins has passed the third professional examination for the degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.) in the subjects of (*a*) Regional Anatomy and (*b*) Materia Medica and Pharmacy.

A COLLECTION OF DRUGS.—Mr. E. Merck, manufacturing and pharmacological chemist, has at the present moment on view at his office, 16, Jewry-street, London, E.C., a collection of drugs which has been prepared and put up in a form intended to meet the requirements of medical schools. The collection has been constructed to show the typical characteristics of each specimen, while the specimens are exhibited in such a way that they can be examined without much handling. It is, however, confined to the organic parts of the materia medica and comprises only the plants themselves and not any preparations thereof. Cinchona bark, for example, is exhibited, but there is no specimen of sulphate of quinine. The limitation of the scope of the collection prevents it from being thoroughly useful to medical students who require to obtain familiarity with the appearance not only of the organic parts of the materia medica but of the derivatives of those parts and also of the inorganic parts. The collection contains many specimens of plants which are not in the British Pharmacopœia and it is unnecessary for the student to know the appearance of these. The more the medical man in later life knows the better, but all teachers are agreed that the present curriculum of the medical student is sufficiently severe and that to teach him more than is likely to be demanded by the examiners is to run the risk of muddling him. The collection is not exhaustive as far as the organic substances are concerned. There are, for example, no specimens of ergot, camphor, colchicum, or cod-liver oil, not to attempt to exhaust the omissions which we noticed. In spite of this criticism we consider Mr. Merck's collection to be thoroughly worth attention, for the idea is a good one and to make the collection complete should not be very difficult.

DIFFICULTIES UNDER THE INFECTIOUS DISEASES NOTIFICATION ACT.—At the meeting of the Cornwall county sanitary committee held at Truro on April 16th the clerk reported that correspondence had taken place between the committee, a medical officer of health, and a general practitioner in reference to the notification of certain alleged cases of diphtheria. A communication had been received from the Local Government Board on the subject which stated that, in the opinion of the Board, the certifier's statement of the nature of a notified case of infectious disease should be accepted unless there was reason to believe that he was not acting in good faith. The Board added that it did not consider it ordinarily the duty of a medical officer of health to examine personally patients who had been notified as suffering from infectious disease with a view to check the accuracy of certificates and where circumstances might render such an examination desirable it should be made after communication with the medical practitioner in attendance and if possible with his coöperation. With regard to the reliance to be placed on bacteriological examination of patients suspected to be suffering from diphtheria the Board remarks that it is advised that a single negative result cannot be regarded as decisive. One examination of a swab from the throat in a given case of diphtheria will not invariably yield evidence of the presence of the diphtheria bacillus in the material, and a careful clinical diagnosis cannot with safety be disregarded in cases which do not on a single test furnish sufficient evidence to warrant their being classed bacteriologically as diphtheria. The Board added that it regarded it as highly improper that an inspector of nuisances should, in any circumstances, collect throat swabs from suspected cases of diphtheria. Eventually the committee decided not to deal with the matter in view of the fact that it had been considered by the Local Government Board.

YORK COUNTY HOSPITAL.—House Physician. Salary £100 per annum, with board, residence, and washing.

YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £110 a year, with board, lodging, and attendance.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Pomeroy, in the County of Tyrone, at Towcester, in the County of Northampton, and at Shotts, in the County of Lanark.

Births, Marriages, and Deaths.

BIRTHS.

CRAWFURD.—On April 11th, at Harley-street, W., the wife of Raymond H. P. Crawfurd, M.D., F.R.C.P. Lond., of a son.

FENWICK.—On April 17th, at Harley-street, the wife of W. Soltau Fenwick, M.D. Lond., of a son.

SQUARE.—On April 14th, at Portland-square, Plymouth, the wife of J. Elliott Square, F.R.C.S. Eng., of a daughter.

MARRIAGES.

BARHAM—LONG.—On April 14th, at Saint Nicholas Cole Abbey, Queen Victoria-street, E.C., Percy Cornelius Barham, M.R.C.S., L.R.C.P. Lond., to Elizabeth Sarah Maud, second daughter of Mr. J. W. Long.

BEALE—MORTIBOY.—On April 21st, at St. Leonard's, Streatham, by the Rev. W. B. Lindesay, LL.D., assisted by Rev. W. H. Tasker and Rev. J. C. Wilson, Hanway Richard Beale, M.B., M.R.C.S. Eng., of Leeds, to Blanche Mortiboy, eldest daughter of Mrs. Mortiboy-Allen.

CRAIG—BROCK.—On April 16th, at the parish church of St. Peter-Port, Guernsey, Maurice Craig, M.D. Cantab., to Edith de Saumarez, [illegible] of Kentish Brock.

[illegible] John's Church, Eastbourne, [illegible] ond, of Greystoke, Upper [illegible] of Mr. John Abbott.

FOWLER—DAVIDSON.—On April 16th, at St. Stephen's Church, South Dulwich, Simson Carstairs Fowler, M.B., C.M. Edin., to Lyndesay Brougham, daughter of the late Rev. Walter Davidson.

[illegible] the Rev. Charles Bostock, of North [illegible], Canon Daniel, vicar of the parish, Edward Protheroe Smith, M.R.C.S., L.R.C.P., of Redditch, Worcestershire, eldest surviving son of Heywood Smith, M.D., of Welbeck-street, to Eva Mary, eldest daughter of E. Ingram Bostock, M.R.C.S., of Horsham.

DEATHS.

CHEESHIRE.—On Sunday, March 29th, at Santa Margherita, Italy, Edwin Cheeshire, F.R.C.S., of Pinner, Middlesex, late Senior Surgeon, Birmingham and Midland Eye Hospital, aged 84.

SPOONER.—On April 17th, at Coupar House, Blandford, Dorset, Edward Monro Spooner, M.D., M.R.C.S., L.S.A., aged 62 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

TO MEDICAL FREEMASONS.

To the Editors of THE LANCET.

SIRS,—Will you allow me to thank most heartily all those who voted for the case of C. P. Hines at the recent election at the Royal Masonic Institution for Boys, by means of which his success was assured?

I am, Sirs, yours faithfully,

April 22nd, 1903. HEATON C. HOWARD.

To the Editors of THE LANCET.

SIRS,—I think it is only right after your kind insertion of my letter in THE LANCET of April 4th, p. 1004, to point out to your readers that at the election at the Royal Masonic Institution for Boys on April 17th both the medical candidates were successful, Samuel Basil Flood being second on the list with 5452 votes and Cyril Patrick Hines being tenth with 4720, and that at the election at the Royal Masonic Institution for Girls on the 18th M. I. Mackay was successful, being fourth on the list with 5611 votes. This result is extremely satisfactory and if, as I almost venture to think, my previous letter has played some part in securing votes for these candidates, I may perhaps be permitted to express my gratification. But although all these candidates were successful, the fact still remains that some system of organisation is needed by which medical votes, which are not required by their owners for candidates in whom they are personally interested, may be pooled and the success of medical candidates thus be ensured. I do venture to hope that this subject will not be lost sight of by the many medical and hospital lodges which, happily, now exist. The voting papers have been issued for the elections at the Royal Masonic Benevolent Institution, but a hasty glance down the list on my part failed to discover any medical candidates.

Thanking you again for the hospitality of your columns,

I am, Sirs, yours faithfully,

April 21st, 1903. LUKE.

THE MEDICAL PROFESSION AND FRIENDLY SOCIETIES.

To the Editors of THE LANCET.

SIRS,—Will you be good enough to express your opinion as to the relation of the medical profession to the National Deposit Friendly Society? Do you consider that the society would be included in the warning about clubs recently issued by the General Medical Council? As far as I can see medical men are required to attend and provide medicine for patients at less than half the usual rate charged to poor patients, and the only compensating advantage is that the payment is assured.

I am, Sirs, yours faithfully.

April 4th, 1903. WALTER COOPER, L.R.C.P. Lond., &c.

*** If our correspondent will forward to us the regulations of the society as to medical men in its employ we will endeavour to answer his question.—ED. L.

TUBERCULIN.

To the Editors of THE LANCET.

SIRS,—I am anxious to know where I may find the latest information as to the treatment of pulmonary tuberculosis by injections of tuberculin, and especially as to the results, disadvantages, and cost of such treatment.

I am, Sirs, yours faithfully,

April 20th, 1903. R. M.

*** The most recent and the most authoritative statements concerning the use of tuberculin in human tuberculosis are to be found in pp. 84–172 of vol. iii of the Transactions of the British Congress on Tuberculosis, published by William Clowes and Sons, Limited, 23, Cockspur-street, London, S.W. We understand that the cost of tuberculin is not less than 8*s.* per bottle and that the outlay necessary for the approved treatment of a case of tuberculosis of the lungs during, say, six months would amount to about £6 or £8.—ED. L.

THE NODON VALVE.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if you would publish the address of the makers of the Nodon Valve described in THE LANCET of April 18th, p. 1108, so that I may get a price list.

I am, Sirs, yours faithfully,

April 18th, 1903. G. H. C.

*** The Nodon Valve can be obtained from Messrs. Isenthal, 85, Mortimer-street, London, W.—ED. L.

CHANCRE OF THE LIP.

AMONG a series of cases demonstrated at the Medical Graduates' College and recorded in the April number of the *Polyclinic* there was one of chancre of the lip. The patient, a youth, had on the right side of his lower lip a rounded sore of considerable size, hardly raised above the surface and having only a very moderate degree of induration at its base. The glands in the submaxillary triangle were much enlarged, forming a very conspicuous bubo. The method of infection could not be traced. Mr. Jonathan Hutchinson, jun., said that it was not at all uncommon for an incorrect diagnosis to be made in such cases, probably on account of the unusual situation and also because chancres of this region did not, as a rule, present typical induration. He mentioned that in the Museum of the Royal College of Surgeons of England there were several examples of extra-genital Hunterian chancres, the true nature of which had been for some time entirely overlooked. Chancre of the lip was obviously from its situation full of risk to those brought into association with the patient and precautions to prevent infection should be adopted. Mercurial treatment should be used and some simple dressing, such as mild mercurial ointment spread on lint, should be kept on the sore. The attention thereby drawn to the sore would assist in reducing the danger of the infection being communicated to other persons.

WANTED—AN ETIOLOGY.

To the Editors of THE LANCET.

SIRS,—I have seen several men who have had intolerable itching of the skin over the shins. They were all men of cleanly habits who bathed regularly and had no skin disease—specific or otherwise. This itching in every case started during cold weather and lasted usually all the winter. What is the cause of this itching? I find unguentum picis liquidæ gives relief if used night and morning. I have been surprised to find so many men troubled in this way.

I am, Sirs, yours faithfully,

April 20th, 1903. AINSWORTH.

POST-GRADUATE WORK IN PARIS.

Syria asks if anyone can direct him to available information regarding the medical teaching institutions in Paris. He desires to spend a few months in Paris this summer to improve his French and would like at the same time to see some surgery at the hospitals.

◆

Pcs.—The Diseases of Infancy and Childhood, by L. Emmett Holt, second edition, London, 1903 (Kimpton, 25*s.*). Lehrbuch der Kinderkrankheiten, by A. Baginsky, seventh edition, Leipsic, 1902 (S. Hirzel, 16·50 marks). These are the most recent works. Pediatrics, by Professor T. M. Rotch, 1896, Young J. Pentland, Edinburgh and London, and A Practical Treatise on Diseases of Children, second edition, 1889, by Dr. Eustace Smith, may also be consulted.

R. A. B.—British medical qualifications are not registrable either in Germany or Austria. Our correspondent could only practise as an unqualified practitioner unless he is prepared to attend the ordinary course of medical study in the countries mentioned.

Mr. J. Penny.—There is no reason to suppose that the medical man whose qualifications are set forth with such minuteness is responsible for the paragraphs in question or for the insertion of the photograph.

Curious.—A district medical officer by residing outside his district ceases *ipso facto* to be medical officer. It is obviously desirable that a district medical officer should be easily accessible.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (27th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1902, which was completed with the issue of Dec. 27th, and the Title-page to the Volume, were given in THE LANCET of Jan. 3rd.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1902 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received: *Northampton Herald, Chester Observer, Surrey Advertiser, Notts Guardian, Bristol Mercury, Dublin Express, Bradford Observer, Daily Graphic, Sanitary Record, Local Government Chronicle, Mining Journal, Hertfordshire Mercury, Blackburn Daily Telegraph, Devon Gazette, Truth, Worcester Daily Times, Yorkshire Post, Westminster Gazette, Evening Telegraph, Essex Daily News, Northern Whig, Belfast News Letter, Dublin Times, Engineer, Literary Digest, Scientific American, Morning Post, &c.*

difficulty that they present to us and the line of practice that ought to be adopted if only we could have before us the complete evidence. But we must first know how often the diagnosis is wrong—that the public, for one reason, may realise that mistakes are inevitable; we must know, too, the risk to life, and those of discomfort, which such a mistake may entail, for there *are* considerable risks as regards the continuance of pain and instability of bowel at any rate; we ought also to know (if it be possible, but I fear it is not) the respective risks from large comparable series of cases treated by operation and without it.

In the matter of risks, too, and of prognosis after operations it is a question whether we always consider the patient enough. Think how dear life is to *you* and put yourself into his shoes. Take such a case as this that occurred to me not so very long ago: a young man with a young wife and family, with a disease that must eventually be fatal, and yet is removeable now at great risk but with some hope of cure. Surgery with its enthusiasm—progressive surgery is always young—says that it ought to be removed and that now is the only time. The real risks are minimised or forgotten and the patient is half urged through his relatives to undergo the chance. The onlooker sees chiefly the *risk* and thinks that it would be better for the sufferer to live his few months certain with those who are near and dear to him than to accept what is too often the remotest chance—and I am inclined to think that it *is* too often the remotest chance, for memory sleeps, in such cases, in a measure, and the disease is considered and the patient is forgotten. The class of cases that I have especially in mind are removals of portions of the intestinal tract for tumours, mostly, of course, of malignant nature. I suspect that in these if we knew the actual facts that the deaths are more than the successes, but the successes all come to the fore and are very striking, the bad results do not appear. And in thus being put out of sight forgotten, or slept over, although it may be conducive to the success of the surgery of the future, I doubt if the individual of the present is treated quite fairly. In this question is involved the frequent complaint of the operator in fatal cases that he had no chance—he was not called in time. But we must not forget that *in time* nevertheless often means for the *individual* that he dies a few weeks or months earlier than he would have done if he had been left alone. It may almost be said, I think, that the physician regards life from a different standpoint to the surgeon. Surgery must be ever pressing toward the mark for the prize of its high calling—the cure of disease and discomfort by operation—and unless its memory of failure or of very partial success were to sleep its onward progress towards its goal might be almost inappreciable. I remember years ago a boy being shown to me as a success in whom an endeavour had been made to obliterate the cavity of a long discharging empyema. But the chief result that was evident to my vision was that whereas there was before, perhaps, one large sinus, now there were six or seven little ones. I cannot think that I could ever have found myself in the position of claiming such a result as a success, but to the surgeon the few sinuses were but as fleabites compared with the advantage of the falling in of the chest which had been produced by the operation.

But I do not forget that medicine makes its mistakes also The mistakes of surgery are more obtrusive; those of medicine are less easy to be sure of and to detect. But I do not doubt that the case of "I and my four daughters who died of drinking Cheltenham waters" may be admitted as typifying the not infrequent mistakes of medicine. That many of them are no less difficult to be sure of is sufficiently and lamentably illustrated by the recent case in the criminal courts where a man poisoned three persons by antimony and even the third time was not so very far off escaping detection. Think, too, of the arsenical beer poisoning, in which instance, unless the cases had occurred in numbers, it may be doubted if we should have discovered them as such. They would all have gone down as cases of alcoholic paralysis, which has been so ticketed for years, and now it may even be possible that there is no such disease.

And this brings me to another class of cases of poisoning where memory may be said to sleep, for I suppose that more persons when they are ill are killed by kindness and anxiety on their behalf even than by drugs. A man no sooner becomes dreadfully ill than all the efforts of relatives and medical attendant are devoted to keeping him up Strong liquid food is poured in, alcohol is poured in, and the ship is gradually but surely sunk There must be many and many a valuable life thus put out of existence, loaded up with meat extracts and alcohol, till the blood which is the life will support the body no longer. You have any one of you often seen, if you wake your memory, the big man or woman very ill with bronchitis or heart disease thus loaded up with food and brandy, and where, if they had only been resolutely starved on water only, they might have had a fair chance of a longer life. But, alas, so deeply ingrained is this tendency to stuff the sick man lest he should sink that I defy anyone to fight effectually against that mighty trio, the patient, the relative, and your own forgetfulness of the belief, nay knowledge, that is in you. I have often used the illustration before—and I will do so again because it represents one of the most important facts in the treatment of disease—of the pig that became imprisoned in the Dover cliff with absolutely no food save a moist atmosphere for its sustenance. It went in a fat pig of 160 pounds and came out after 160 days alive but a lean pig of 49 pounds. Think of the number of sick people to whom, or for whom, that offers a valuable lesson as to treatment. The bulky fat man or woman with small congested and bronchitic lungs and kidney and liver congested also—I often long to put that patient on a very restricted diet of almost water. But there are very few patients, and fewer still of the friends, who have sufficient faith in a rigorous abstinence of this sort to allow one to carry it out. You can carry out a very restricted diet for aneurysm, in which case the patient is not obviously so seriously ill. You can carry it out under the name of the "Salisbury treatment," when men or women find their size inconvenient, but try severely to restrict food when anyone is very ill with such conditions as I have mentioned and it is a very different matter.

I spoke a minute ago of our forgetfulness of the knowledge that is in us. Let me say a word more on this head. We forget in a wide sense our own experience. For example, I often see a case that I think needs opium but where that drug has been withheld because of a supposed or actual disease of the kidney. There are few ideas more prevalent amongst us than that it is dangerous to give opium in cases of renal disease. That doctrine once, I suppose, crept out of the mouth, or out of a book, of some teacher of repute and has been handed on and on with increasing volume, till to-day it has become a prevalent belief. I have, I believe, heard it myself out of the mouth of a lecturer and when I have accompanied him to the wards I have found his patients taking, with renal dropsy, five-grain doses of Dover's powder every four hours. His memory slept. Many of you, I doubt not, withhold opium where you would otherwise have given it because there is some albumin in the urine and yet if you think back you will remember that you have often been obliged to have recourse to it and when you have, never, so far as you can remember, with any adverse result. I ask myself whether I have ever seen any harm come of the use of the drug in such circumstances and all I have to say is that years ago in a case of granular kidney, where the patient was very seriously ill, I did give a dose of morphia by subcutaneous injection from which he never woke; but I wish my memory *had* slept over *that* case, for I am quite convinced that its recollection has often unjustly hindered my recommending the use of morphia when from my heart of hearts I believed that the drug administered in this way was the only one likely to relieve the patient's sufferings At any rate, there is no doubt that morphia carefully administered by the *mouth* in these distressing cases of cardiac asthma, in renal disease, is not dangerous; and, indeed, they can often enough only be relieved by the same drug administered subcutaneously. The only cases in which I am afraid to give opium, and in which I feel sure there is a very real danger, are where the blood is dammed back in the lungs in chronic bronchitis or an extensive pleuritic effusion. This does not include an ordinary pneumonia, where, as you well know, opium is often a most valuable drug.

And this sleeping memory is ofttimes very unfortunate for our diagnosis. In thus making us forget what we have seen we too often miss the broad points of a case which, if seized, would point unmistakeably to a correct opinion. Thus it is, too, that we are inclined to pin our faith too absolutely to the latest achievement of research and are again very likely to go wrong altogether. I have seen striking examples of this at one time and another. Within the last year, for example, it has twice occurred to me to see cases where the presence of Widal's reaction had made the diagnosis lean in the direction of typhoid fever, where I venture to think that without that test the prominent facts were all in another direction. In each case there was an intra-peritoneal abscess. Diagnosis is never a question of one symptom, it is always a balance of probabilities, and it needs to be remembered that often enough the balance is exceedingly delicate. Still, I think that mistakes would be fewer were we more to content ourselves with gathering up the salient features of a case instead of allowing ourselves to be diverted by interesting subtleties.

Then memory sleeps to-day—alas too often—over the great facts of heredity and environment. In what single disease, as we know it to-day, can we say that the sway of heredity is undisputed as it once was? Take cancer—and its occurrence is attributed to the Thames—or I suppose some other river—valley, to a particular house or houses, or to some hypothetical germ which we are trying hard to find and shall probably before long succeed in demonstrating. For tubercle we have its germ and its cure—the open air. There was a time when the insurance offices loaded you heavily for a consumptive father, and refused you altogether for a weak-chested mother. They surely must relax their penalties now. Acute rheumatism is due to a germ; other forms of arthritis also; and even gout, by being an arthritis, lies under a suspicion. All these diseases were supposed to be strongly hereditary, but now—oh dear no! that is quite out of date. *But a poor fellow comes into my room* with bolting eyes, panting breath, and a heart that has run amuck—tachycardia we call it and attempt to treat it as of course we must do—but [illegible] 's only a symptom. His *dis*[illegible] of the nervous system wit[illegible] ed with the fact that the great world has used him up in its relentless efforts to add to her gains. This man's brother has a slow creeping paralysis of many years' duration and *he* has Graves's disease. Yes, my friends, bear this in mind, that the world will use you up if you let it do so. And when you die before your time it will say—Ah! poor fellow, it is a pity he worked so hard. And that is all the thanks you will get, and it is a poor sort of bread-and-butter for your wife and children. You had better, everyone of you, take a good holiday every year and enjoy its inspirations—for they are many—while you have the opportunity, and what is more the desire, and keep your health. For the world *is moved by forces that it knows not* of and as such is instinctively selfish, and it will use you for its own purposes and grind you wonderfully small in its everlasting mills, and that without the smallest ultimate advantage to you.

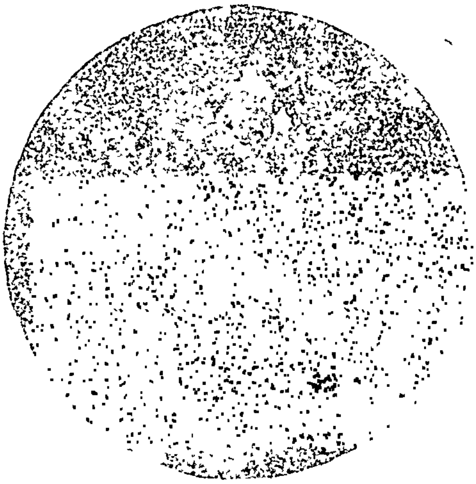
Here is another case that comes before me as I write of a similar kind and which teaches the same lesson. An officer in the army ascribes all his ailments to overwork in preparing for an examination. At any rate he never afterwards felt well and when summoned to go abroad in the Boer war he was so limp that he could hardly put one foot before the other. Yet when in it he bore himself so that his enemies had a care for him and he seems to have obtained both health and credit. But as soon as he came home, expecting to remain well for the future, he speedily fell back into his old limpness, in which he suffers badly from depression; his bowels became obstinately constipated; he could not think; he could not remember; he could not even write his letters sometimes, for his hand seemed to forget its cunning. He attributed all his woes to his constipation and his liver—and there are those, it must be admitted, who would entirely agree with him. Unfortunately, I am not one of them, else haply I might believe that a little medicine might put him all right. But I know otherwise. I know that his father was like him, suffering similarly with depression and like his son of a worrying and anxious temperament. I know, also, that I have to subvert a deeply set characteristic, to cure which it is necessary for him to let the present be as nought, while he sets himself to build him *a bridge of hope out of the relics of the well-nigh forgotten* past. No one who has gone through the experience will think this an easy treatment, for it discloses to the anxious mind precipices and possibilities on each side of it that may well make even a stout heart quail and these hearts are for the moment not stout. And yet, if the memory does not too soundly sleep, it is clear since, to take the particular case, the man went through an arduous campaign there can be no disease and that there can be nothing that in the future he may not outstrip and disentangle himself of. But memory sleeps, and men make too much of these mental and nervous aberrations; they think they are important when indeed they mean little, for I take it that they are often no more than the equivalent of the twinge of pain in a peripheral nerve or the more prolonged neuralgia of some one or other of the organs about which one would never think of taking a hopeless or even a gloomy view.

How often people are troubled about their memory when there is in truth little fault to find. I suppose there is no commoner cause than this for seeking the advice of a medical man—"My memory is so bad," and this is supposed *to mean that the brain is going.* The memory sleeps It may not be a very convenient recreation but it is not one of ominous import. For in the present day with the multiplicity of detail that attempts to find an entrance the brain of man tends to become somnambulistic. As you well know, the somnambulists, or some of them, although remembering nothing of their somnambulistic actions or observations, will nevertheless sometimes give certain evidence that although they cannot recall them they are yet within the register of the brain. A case of this kind is narrated by the late Dr. William Carpenter in his "Mental Physiology." A man dreamed a dream with certain peculiar conditions of crawling lizards as its subject for the origination of which no explanation was forthcoming, and he was telling it at the breakfast-table when he came downstairs, when it was pointed out to him that it had obviously been conditioned by the clock upon the mantelpiece which *he could not remember that he had ever seen. But of course* he had taken it in when he had been talking the night before, and there it was in his subliminal consciousness, all unknown to his conscious self. Now this condition is quite a common one nowadays. One's brain being intently occupied in one direction, some fact in quite a different direction is told and apparently intelligently accepted. And yet thereafter there is not the slightest recollection of the fact. The fact is probably there all the same and your mere forgetfulness of it is no matter of consequence. A stronger case than that might be given of the man who, writing many letters in the day and keeping no register of them, may have written a particular letter, even going into a fair number of details, and yet afterwards be quite uncertain whether he has written the letter or no.

Another case of a sleeping memory that occurs to me is the exceedingly unpleasant one of the sudden cessation of thought that occasionally comes to some in the very middle of making a speech or extempore address. Suddenly in the full flow of thought a blank comes and they know not what of the future, while memory and thought take a nap. How common it is, too, that after sleep memory wakes behind the man and for some seconds he cannot tell where he is and, more, could not speak *of any fact of his daily life save only* that he exists. Uncanny, indeed, are many of the sudden jolts and stoppages in the even flow of nervous action, and so is the sudden intermission of the heart to some people, but they are momentary and unimportant if one can only believe it. They are well typified by the sudden jolts in your electric circuits which restore themselves almost as soon as they occur.

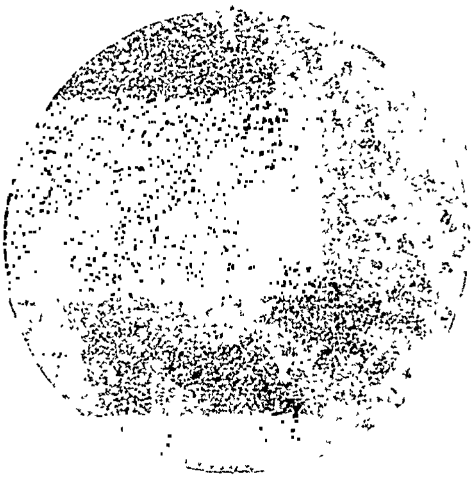
The brain is subject to the same conditions and laws as other organs; only its expressions of illness vary and much of what is pain in other parts becomes a disturbed sensation of other sort—disordered thought, disordered sense of this or that order. I saw a lady only this morning who after a bad migraine—it is truly a very bad one—perceives a bad smell, which is clearly a brain smell, not a nose smell—that is, it is generated in the centre and not at the periphery. If we could but in all these mental phases remember this, that brain sickness must express itself in terms of brain function, intellectual, subliminal, of the special sense centres, &c., as the case may be, how much misery would be saved, how much more rational would our advice be, how much more successful would the results in all probability turn out. Why should a man *with a dull head or a sensation of worms* crawling about inside his head, or with a memory worse than it was of yore, and so on, think that he is losing his reason [illegible] any more than [illegible] his limb is on t[illegible] labouring under [illegible] which he is prone to take very [illegible] *brain maladies of more or less* similar origin and which, equally with those of the subordinate viscera, will certainly have that natural tendency towards recovery that in those leads us to expect it. But memory sleeps and the brain, which keeps all the rest in normal appearance, a fact suggesting that while the amount of serum given was sufficient to affect the organisms in the bubo it was too small to influence the bacilli throughout the body generally. In this connexion it must be remembered, however, that the serum causes no such alteration "in vitro." This local effect of the serum on the bacilli in the inguinal bubo is shown in the accompanying illustration (Fig. 1), where the coccoid degeneration, the indefinite outline of the organisms, and the total loss of bipolar staining are very apparent. These appearances may be contrasted with those shown in Fig. 2, where the characteristic bipolar staining of the bacilli present in the spleen is very evident.

FIG. 1.



Degenerated plague bacilli from inguinal bubo after subcutaneous administration of serum. Fourth day of illness. × 1000.

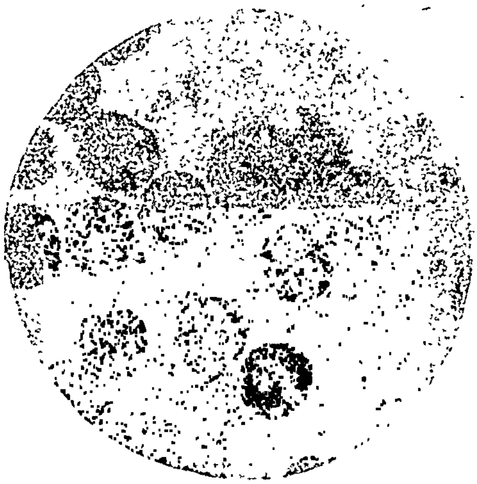
FIG. 2.



Showing characteristically stained plague bacilli in spleen of same case. Fourth day of illness. × 1000.

As in some measure tending to confirm the view that those changes were due to the serum administered another fatal case of plague, in which curative serum was given both subcutaneously into the drain of the affected glands and also intravenously, may be cited. This patient was admitted to hospital on the fifth day of illness with a large and characteristic plague bubo in the right inguinal region. She was so seriously ill that no hope was entertained of her recovery, but 80 cubic centimetres of Yersin's serum were given subcutaneously by Dr. J. Brownlee into the inner aspect of the affected thigh. The following day she appeared much worse and 100 cubic centimetres were again given subcutaneously into the abdominal wall and 40 cubic centimetres intravenously. The same evening the patient died suddenly from acute heart failure. If the degenerative changes just described were the result of the local action of the serum on the organisms in the bubo it might reasonably be expected that similar changes would be found in the organisms present in the spleen and other tissues if the serum were administered intravenously. These conditions were actually found in the case just described and in the accompanying illustrations (Figs. 4 and 5) the changes in the morphological characters of the bacilli after the combined subcutaneous and intravenous administration of serum are clearly shown.

FIG. 3.



Bacillus pestis from bubo prior to administration of serum. Shows well-marked polar staining. Gentian violet,[2] × 1000.

From an examination of these two cases it became apparent that a hitherto unnoticed mode of action of plague curative serum was evidently at work—viz., a directly bactericidal effect. In any disease of bacterial origin the effects produced—as evidenced by the symptoms of the disease—are generally ascribed not so much to the presence of the bacteria themselves (except in those instances where their rapid multiplication mechanically obstructs the blood-vessels—e.g., anthrax) as to the specific effect of the toxin formed by them. To combat such a disease the remedy employed has to perform a double function: (1) the toxin

FIG. 4.

---

[2] This illustration, as also the preceding (Fig. 2), gives a very deceptive impression of the number and appearance of bipolar-staining bacilli. The number of normally staining organisms on the cover-glass was in reality very considerable.

already existing has to be neutralised, and (2) the bacteria have to be destroyed or their growth inhibited so that the further production of toxin may be lessened or arrested. The more or less considerable improvement in symptoms which has been found to follow the administration of Yersin's serum is in itself sufficient proof of its powerful antitoxic effects. From the microscopical observations just detailed, however, we have anatomical evidence of the bactericidal properties of the remedy. The serum apparently induces a degeneration in the bacilli themselves and these marked structural changes are bound to be associated with a considerable interference with their toxin-producing power. The remedy, therefore, strikes directly at the proximate cause of the disease—the bacilli—and also neutralises the toxins which have been produced. The evidence so obtained from microscopical examination, not only encouraged the freer exhibition of the remedy, but also gave a clue to the method which was ultimately found to yield the most beneficial results. Adequate doses had first to be administered locally in the drain of the bubo, so that the maximum bacillary degeneration might be speedily effected and the production of toxin arrested, and further, in order to reach those bacilli which might have escaped to the spleen or other organs and also to neutralise the toxin already existing in the blood the intravenous method of injection was indicated. Anatomically, it has just been shown that the serum has a local specific action on the bacilli in the bubo and that when introduced into the general circulation a like change was observed in those bacilli which had become lodged in the viscera. The microscopical evidence of bacillary degeneration in the spleen (shown in Fig. 5) encouraged one in the belief that larger doses of the serum intravenously would produce a still more decided change in these bacilli. Subsequent trial of this method was followed by clinical results which seemed to justify this assumption, but as all the cases so treated fortunately recovered no bacterioscopic information could be obtained of bacillary degeneration in deep organs. At this stage it may be of interest to recall briefly some of the cases in the earlier outbreak of which the following are the charts (Charts 1 and 2).[3]

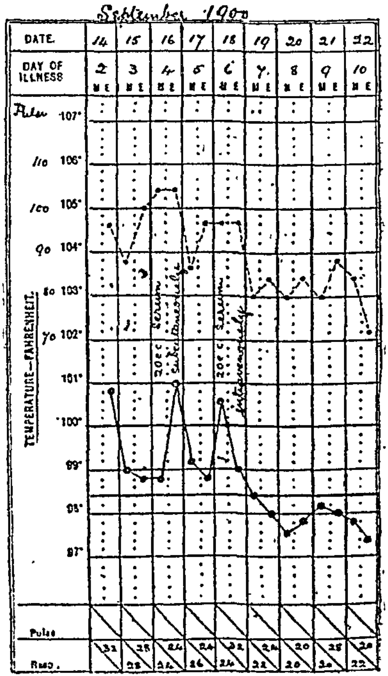

CHART 2.

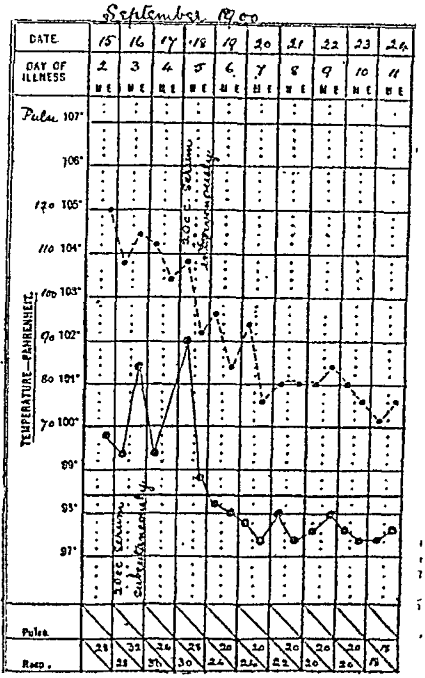
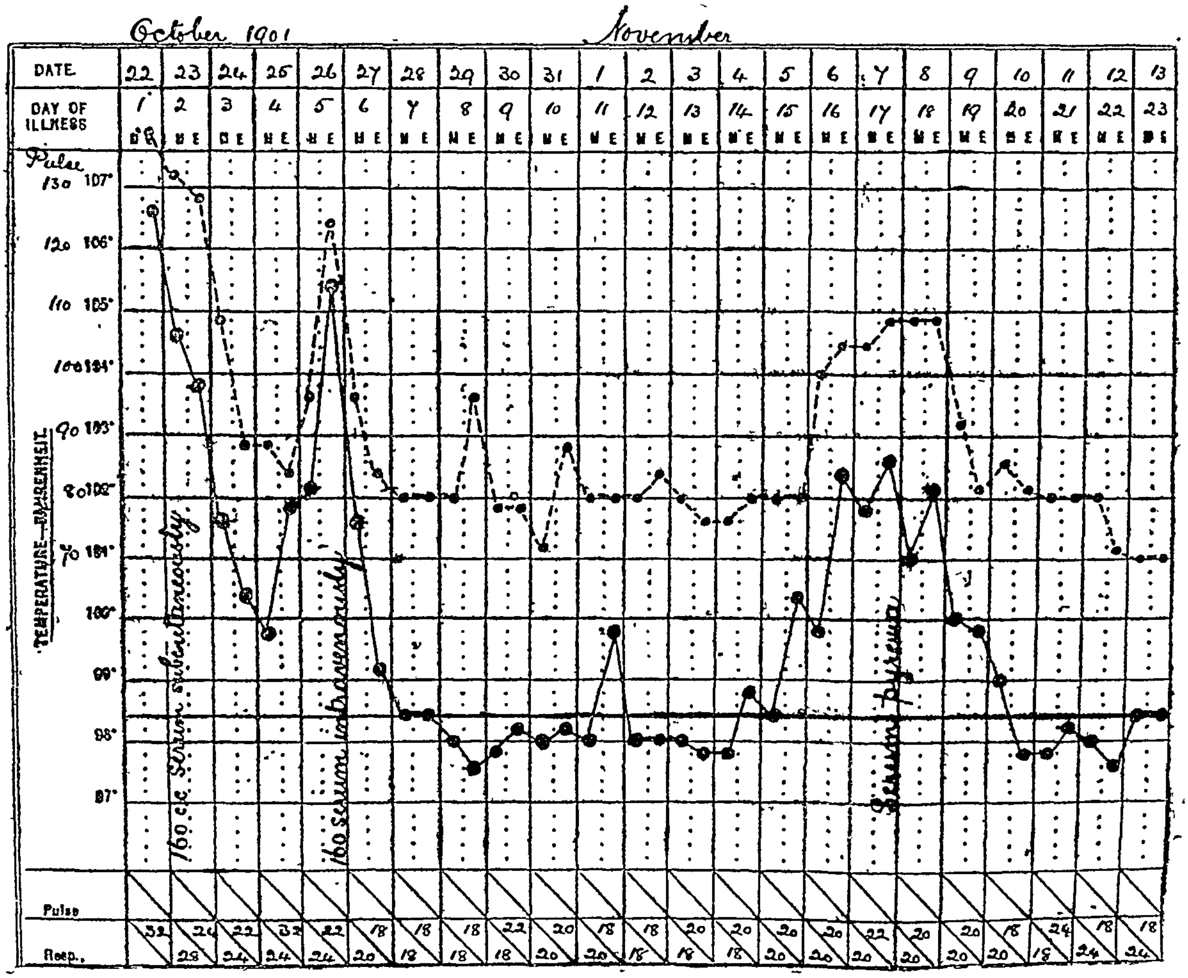


---

[3] Report on certain cases of plague occurring in Glasgow in 1900, by the medical officer of health, pp. 42 and 51.

It will be observed that after the subcutaneous injection improvement, as evidenced by fall in temperature and pulse, set in, though this was of temporary duration. On the other hand, when the intravenous method was employed the improvement was more decided and permanent. At the time when these cases were under observation no experience of the serum treatment of plague had been acquired and the remedy was used in a somewhat tentative manner until familiarity with its effects led to its freer exhibition. The cases just cited, though of a mild type, were proved to be genuine cases of plague, not only on clinical grounds but also by a complete chain of bacteriological evidence. It will be noted, however, that the serum was given in comparatively small doses. In the second outbreak of plague even more severe cases than were met with in the first epidemic were treated with comparatively large doses of serum, subcutaneously and intravenously, the experience already gained having encouraged this practice. The results were eminently gratifying, as several exceptionally severe cases recovered under this more energetic line of treatment, but, of course, in these fortunate circumstances no evidence could be obtained of degeneration induced in bacilli throughout the body. The following two cases from the second outbreak are selected as being of an exceptionally severe type.

CHART 3.

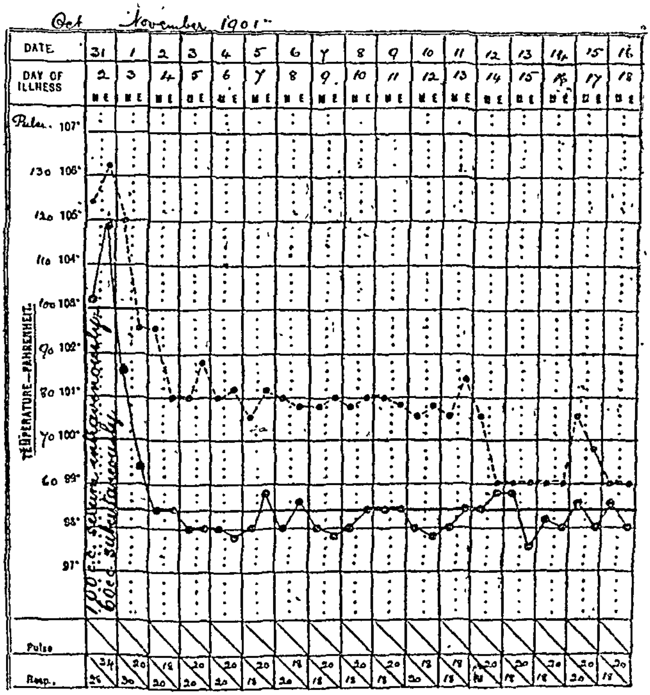


Temperature Chart of Case 1.

CASE 1.—A woman, aged 23 years, was admitted to hospital on Oct. 23rd, 1901. She was first seen by Dr. J. F. Fergus and the following is his note on the condition of the patient prior to her admission. "About 11.30 on the night of Tuesday, Oct. 22nd, I was called to see a young lady, an employée in a hotel in the city. I found the patient violently ill, complaining of severe pain in head and body, vomiting slightly and very much flushed, the face being markedly so, and the conjunctivæ suffused. She seemed seriously ill and answered my questions in a curious, slow, scanning sort of way. I had already seen this patient about two or three weeks previously for a suspected gastric ulcer with purely gastric symptoms, and the pain on the present occasion being referred principally to the abdomen I at first thought that the present illness might be a return of the former, but on taking her temperature it was 106·6° F. and her pulse was running close on 140. As she was in extreme pain I gave her one-third of a grain of morphia hypodermically and stayed for some time to watch the case. I then made a more systematic examination of her and found a generalised scarlet rash on the trunk and also to some extent on the limbs. On palpation there was no special pain in the abdomen but in the right groin below Poupart's ligament was an exquisitely painful glandular swelling of about the size of a filbert. There were no swelling of the lymphatic vessels in the leg and no injury or abrasion of the limb. She had a slight sore throat of no great severity and without spots and there was no enlargement of the cervical glands or of those in the axilla. The clinical features of this case seemed to me to present an almost typical picture of the classical description of bubonic plague and before leaving the hotel I arranged for her immediate removal to Belvidere Fever Hospital. My suspicions had been particularly aroused by the assistant housekeeper mentioning casually that the patient had been complaining of a smell in the dessert-room where she worked and on my making more particular inquiries I learned that rats had been dying throughout the hotel in greater numbers than usual."

When admitted to hospital the patient was evidently acutely ill; the face was deeply flushed, the eyes were suffused—in fact, congested—and the pupils were widely dilated. The tongue was moist and clean and showed no enlargement of the filiform papillæ. The fauces were slightly congested. The skin was hot and dry and both the trunk and the limbs were covered with a uniformly bright erythematous rash which momentarily faded under pressure, showing the skin to be perfectly pale and devoid of any of the usual yellow staining commonly seen in scarlet fever. The expression of the face was dull and heavy yet anxious and the patient, though able to answer questions more or less intelligently, was evidently only half-conscious of her surroundings, for it was subsequently ascertained that she had no recollection of the bubo being punctured or of the first administration of serum. The condition of the bubo was as described in Dr. Fergus's note and so exquisitely tender [illegible] bubo by means of a sterilised hypodermic needle and from this cover-glass films were made and glycerine agar tubes were inoculated. *Immediate examination of the films*, after staining with gentian violet, showed the presence, though in comparatively small numbers, of a short bipolar-staining bacillus morphologically identical with that of plague. When treated by Gram's method the bacillus was decolourised. The inoculated tubes were incubated at 37° C and 36 hours later a faint white surface growth had appeared composed of small translucent colonies with serpiginous margins. Microscopical examination of cover-glass preparations made from these colonies showed a bacillus morphologically ide[illegible]ning reactions to, [illegible] the cultures an[illegible] the organism as [illegible] 160 cubic centi[illegible]ered subcutaneously on the same afternoon, the seat of injection being the thigh and in such a position that the serum would be absorbed by the lymphatics draining towards the affected glands. *This was immediately followed by a very rapid and striking amelioration* in both the local and general condition of the patient, improvement setting in within six hours after the serum injection. The temperature abruptly fell from 106·6° to 100·4° the following evening and with this was associated a *corresponding reduction in the pulse-rate from 132 to 88.* The patient was now perfectly conscious, the severe headache had entirely disappeared, and she spontaneously expressed herself as feeling much better. These favourable symptoms were associated with equally satisfactory changes in the bubo, the pain and tenderness of which were so much alleviated that it could be freely palpated without giving rise to any discomfort. This improvement, however, was short-lived, for on the next evening the temperature rose to 101·8° *and during the succeeding 24 hours it continued to rise till at six o'clock on the evening of the 26th (the sixth day of the illness)* it stood at 105·4°. The pulse also was correspondingly rapid and more compressible than formerly. The bubo had increased somewhat in size and had again become acutely tender, whilst her general condition reverted to that on admission. At this stage 160 cubic centimetres of serum were injected intravenously into the median basilic vein, and this was happily attended by even more gratifying results than those witnessed after the first administration of serum. Within 36 hours the temperature had fallen by a rapid crisis from 105·4° to normal and with the exception of a trifling rise on Nov. 1st the latter figure was never exceeded during the following week. Defervescence was accompanied by a rapid and complete disappearance of all the threatening symptoms, by first a lessening and then by a complete cessation of pain in the bubo, and by a rapid return to consciousness and feeling of well-being. During the next few days the bubo enlarged somewhat and became highly inflamed though not at all

CHART 4.



Temperature Chart of Case 2.

painful. By the end of the second week it was quite fluctuant and in appearance resembled an acute abscess. Spontaneous resolution, however, occurred without external rupture. Convalescence was rapid and complete and with the exception of some sharp febrile disturbance during the third week—due to severe articular pains consequent upon the administration of the serum—it was uneventful. The patient was dismissed on Dec. 12th and at this date the bubo was represented by a small horizontal chain of enlarged and indurated glands, quite devoid of pain and more or less firmly adherent to the skin and subjacent tissues.

To meet the extreme urgency of the case it was decided to administer a large dose of the serum subcutaneously (160 cubic centimetres as compared with from 20 to 60 cubic centimetres in former cases). So far as the immediate result was concerned the treatment seemed to be successful, but the improvement was short-lived, for, as has already been noted in the mild cases, the temperature quickly rose again and the patient's condition became almost as bad as before. The local symptoms having subsided somewhat, but the general condition of the patient pointing to increased action of the toxins on the system, it was considered advisable to administer more serum intravenously. 160 cubic centimetres were accordingly introduced into the median basilic vein. Almost immediately thereafter a marked improvement occurred which continued until nine days later when the usual serum pyrexia made its appearance (Chart 3).

The second case was also of a very severe type and occurred in association with the preceding.

CASE 2.—A woman, aged 33 years, was admitted to hospital on Oct. 31st, 1901. The patient had been "out of sorts" for a few days prior to the actual commencement of her illness, but the onset of severe symptoms occurred quite suddenly on the morning of Oct. 30th. She then became ill with violent headache, sickness, and vomiting, and pain in the left groin. All these symptoms rapidly increased in severity during the next 24 hours and on the following morning she was admitted to hospital in a profoundly prostrated condition. As in many respects the case was precisely similar to the preceding it is perhaps unnecessary to enter more fully into the details of the illness. The constitutional disturbance was considerable, the temperature being 104·8° F. and the pulse being 124. A relatively small but exquisitely painful bubo was present in the left groin about one and a half inches external to the spine of the pubes. The glands affected were those of the horizontal inguinal chain and so sensitive were they that the slightest pressure caused the most acute agony. On account of the gravity of the illness it was decided to at once administer serum by the combined method. 60 cubic centimetres were accordingly introduced into the lymphatic drain of the bubo and 100 cubic centimetres were introduced under hydrostatic pressure by means of a transfusion cannula into the median basilic vein. The reasons for administering serum both subcutaneously and intravenously have already been discussed and a reference to Chart 4 is sufficient to indicate the beneficial results which followed upon this line of treatment. Within 36 hours the temperature fell from 104·8° to normal and subsequent records never exceeded 98·8°. The pulse-rate was likewise lessened by 50 beats per minute. As in the previous case, a striking diminution in the tenderness of the bubo occurred a few hours after injection, its further development appeared to be arrested, and spontaneous resolution occurred without rupture and without any apparent softening or inflammatory reaction. Convalescence was rapid and complete and when the patient was dismissed on Dec. 12th, 1901, the site of the bubo was indicated merely by two small indurated but perfectly painless glands about one inch outside the pubic spine.

Profiting by the experience already gained in the previous case serum was at once administered by the *combined method.* It was hoped by this plan to arrest the further production of the virus locally in the bubo and also to completely neutralise the toxin circulating in the blood. Both of these expectations were fulfilled, as was shown by the rapid and permanent improvement which took place locally and generally. The theory held regarding the previous case was that the primary fall of temperature depended largely upon the destructive action of the serum on the bacilli in the bubo and the neutralisation of the toxin in its immediate vicinity. The secondary rise, on the other hand, was believed to be due to the toxin already circulating or present in the various organs—e.g., the spleen, to which some bacilli might have gained access, and which, having escaped the local action of the serum given subcutaneously, continued to exert unimpaired their toxin-producing power. It must be admitted that the number of cases is too small to warrant general deductions, yet the experience gained is at least sufficient to suggest a more extended trial of what, in our limited experience, seems to be the most efficient method of administering plague serum. Beginning with the milder cases we find temporary improvement following upon subcutaneous injection, the final improvement depending upon the subsequent introduction of the remedy intravenously. Finally, it becomes evident from due consideration of the degree and nature of the improvement effected by the different methods that in severe cases the most satisfactory results are obtained by the simultaneous administration in adequate doses of subcutaneous and intravenous injections of Yersin's serum. This method, as is well known, was first suggested and employed by Calmette and Salimbeni during the Oporto epidemic in 1899.[4]

Conclusions.—The experience gained during the two recent outbreaks of plague in this city seems to warrant the following conclusions: (1) that Yersin's serum is a remedy of the greatest value in the treatment of bubonic plague; (2) that its action is bactericidal, as shown by the degeneration induced in the bacilli, as well as antitoxic; (3) that this double action of the serum is best secured by its early administration in large doses, both subcutaneously into the lymphatic area which drains towards the bubo, and also intravenously; and (4) in very mild cases subcutaneous injection alone will probably suffice, but in severe cases the combined method should be employed. For these latter the initial combined dose should be perhaps from 150 to 300 cubic centimetres, the proportion given intravenously varying with the relative severity of the general symptoms.

Glasgow.

A CASE OF TRANS-SACRAL REMOVAL OF AN INTUSSUSCEPTION WITH MALIGNANT GROWTH BY A METHOD UNUSUAL AT PRESENT.

BY ARTHUR E. BARKER, F.R.C.S. ENG.,
SURGEON TO UNIVERSITY COLLEGE HOSPITAL, ETC.

A BRIEF record of the following case may, I venture to think, prove useful to those who like myself are much exercised in their minds as to the proper course to take in regard to the treatment of carcinoma of the rectum. On the one hand we have to decide whether simply to palliate by colotomy or on the other whether a more radical operation for the removal of the growth is called for. And if we answer the last question in the affirmative we have to settle in our minds which of many procedures holds out the best prospect of permanent success. The pathological condition, too, met with in this case has many points of interest.

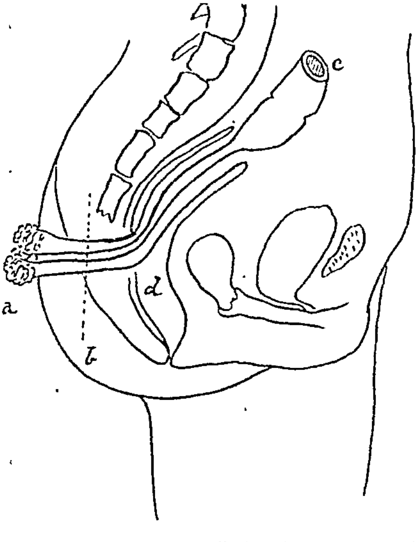
A single woman, aged 52 years, was sent to me on April 29th, 1902, by Mr. F. Hart-Smith of Leominster with the following history. She was reported to have had for a couple of weeks before being seen a discharge of blood and mucus from the bowel without obstruction, distension, or pain. On examination her medical man felt an ulcerated mass in the rectum which he took to be carcinoma, in which, as it turned out, he was quite correct. I was surprised, therefore, when I first examined the rectum to find nothing abnormal with my finger, although the latter came away covered with blood-stained mucus. I then introduced a long glass Ferguson's speculum and examined with a good electric light. But nowhere could I see anything abnormal except some blood and mucus which came from high up. Nevertheless, I felt sure that my old friend's diagnosis was correct and that I was unable to find what he described because it had slipped up. I took the condition to be one of a carcinomatous ring causing an intussusception which had become reduced. This, although not very common, is a condition most likely familiar to many surgeons and one on which I have several times operated. I wrote in this sense to Mr. Hart-Smith and recommended large high-reaching enemata. A week or two later he wrote that the enemata had brought away an *enormous* quantity of fæces, but that he had never been able to detect the rectal growth again. But, on the other hand, he had felt a lump in the left groin. The patient was much relieved at first, but towards the end of May obstruction set in which was not overcome by enemata and on June 6th she was admitted into hospital.

---

[4] La Peste Bubonique, par Calmette et Salimbeni, Annales de l'Institut Pasteur, Decembre, 1899, p. 899.

The growth was now again felt in the rectum close to the anus and the finger could be passed round it on all sides or into its central lumen. There could be no doubt that we had before us a growth seated at the apex of an intussusceptum. The only question which remained was whether to perform a palliative colotomy or to attempt to remove the growth. As the latter was ring-like and seated on an intussusception I felt that its complete excision ought to be easy. But the question how was the difficulty. As the mass had at one time receded altogether out of touch and sight from the rectum it appeared to be clear that the meso-sigmoid must be very mobile and that the ring of neoplasm probably belonged to the sigmoid flexure. And having had some favourable experience of the removal of such growths through the groin it occurred to me that if it could again be reduced I could more easily and completely excise the growth from the groin than from below and make an "end-to end" junction of the bowel from there as I had recently done in other cases.

On June 12th, therefore, I opened the left groin and tried to pull up the intussusception within reach. This failed though I could feel it jammed in the pelvis. The wound was closed and the patient was put in the lithotomy position. I then dilated the anus and tried to pull the intussusception down for excision through the anus. Here, too, I failed, as it appeared to be fixed too firmly. Until the wound in the groin was healed nothing further was done. Then on July 10th I proceeded to remove the growth by the trans-sacral operation, employing a method which appeared to me to be novel so far as my reading and observation go.



a, Growth drawn out for excision at line *b*. *c*, Flexure intussuscepted into the rectum, *d*.

In the first place, a curved incision as usual was made, commencing on the left side of the lower part of the sacrum and ending in the middle line, a little below the tip of the coccyx, with the curve, of course, to the right. Through this opening the whole of the coccyx was dissected out with as little damage to its muscular attachments as possible and then about an inch of the lower end of the sacrum was removed with bone forceps in the usual way in such trans-sacral operations. Through the opening thus made an incision was made in the soft structures in the middle line until the wall of the rectum was exposed. Through it the mass of the intussusception could be felt easily at about the level of the coccyx. Over it the rectum was divided in the middle line and through the opening thus made the intussusceptum was drawn outside the intussuscipiens. There was no difficulty in doing this or in obtaining complete control over it. The left index finger was now thrust up the lumen of the intussusceptum while the thumb closed upon its outer surface above the growth. But although there appeared to be no small bowel intruded between the two layers of the intussusceptum it was thought better, before proceeding further, to open the outer wall of the intussusceptum to make quite sure. When by this opening it was seen that no small intestine was included between the serous layers, the latter were sutured together by transverse linen-thread sutures passed from without through all the coats into the central lumen of the intussusceptum. This ring of sutures was placed well above the growth and when completed the whole intussusceptum was cut off transversely about a quarter of an inch below the line of suture. The edges of the cut surface were then overcast with a continuous suture and when the stump had been cleansed it was allowed to slip back through the opening in the intussuscipiens and the latter was closed with a continuous suture. The whole of the wound was now covered by an apron of gauze which was thrust into all its pockets and filled with strips of iodoform gauze and the skin was sutured at both ends, leaving the wound open at its middle.

The patient bore the operation well and the large wound closed slowly but steadily. There was a slight fæcal discharge through the wound in the intussuscipiens for some days from the seventh day after operation, but it ceased soon after one stitch was discharged. The patient left the hospital on August 14th, a little more than a month after the operation. She came to show herself on Oct. 14th, looking quite well and without any trouble except some discomfort when sitting down for long and leaning back. She had complete control over her motions and over flatus, which was only to be expected as there had been no interference with the sphincter apparatus or its nervous supply except by the initial stretching of the anus, which, as we know, is soon recovered from.

In this mode of dealing with a growth seated on an intussusception I followed a plan which I proposed at the Royal Medical and Chirurgical Society in the year 1887,[1] in replying to a question put to me by Mr. C. Heath, *apropos* of a somewhat similar case of his own. It was comparatively easy to carry out here and I venture to recommend it for similar cases. The advantages in a case suitable for its employment are obvious. The loss of the coccyx is a small matter and the rest of the operation can be carried out without interference with the sphincters or any other essential structure. The peritoneum is, of course, opened for a moment, but under such conditions that any risk of infection is small and easy to meet. And the fact that the growth is seated on an intussusception which allows of excision far above the invaded area appears to me to give a good prospect of non-recurrence. Possibly it may be of limited application, but I am not so sure. It might be possible in some cases of carcinoma of the sigmoid flexure or higher portion of the rectum without intussusception to open the rectum below the growth and to pull down the growth, as in this case, and so produce the condition of things which was here found to be so easily dealt with.

In the debate in 1887 referred to my description of this operation proposed then, so far as I know for the first time, ran as follows.[2] Replying to Mr. Heath, who inquired what was to be done in a case where the intussusception could not be drawn outside the anus, as in a case which he had had, I said: "I should certainly do a laparotomy in that case. But if I were dealing with a condition exactly like that to which he refers I should be inclined to excise the whole intussuscepted mass (*in situ*). I remember his case very well and I think had it been possible to diagnose it before operation began the whole intussusceptum might have been excised without a very great deal of risk to the patient. I have for a long time past had an idea of an operation for such a condition which I should like to have an opportunity of carrying out. Given the intussusception I should search for the upper part. I would make use of Czerny's suture to put in a row of stitches and stitch up the whole of the upper margin and *afterwards cut off the intussusceptum through the convex margin of the intussuscipiens*, which would afterwards be closed by suture. It is quite clear to my own mind that one would imitate nature by that method—that is to say, take the intussusception as it stands and, taking the point where nature usually throws out a quantity of lymph, put in a row of sutures without disturbing the part in the least, cut off the intussusceptum through the longitudinal incision, and then sew up the open gut."

[1] THE LANCET, May 14th, 1887, p. 980.

[2] Proceedings of the Royal Medical and Chirurgical Society, 1887, p. 260.

For some time after that I had no opportunity of trying this method proposed in 1887, but later I used it in an ordinary case of intussusception in a child. The case was published with figures explaining the method.[3] Later still Dr. Widenham Maunsell proposed the same method and it is usually called by his name. In the case now recorded it was used in the trans-sacral operation, but the principle is the same.

Some of the speakers in the debate referred to seemed to think that the condition in the rectum in which a new growth is seated on an intussusception is not so rare as I was then inclined to think. If this is so such an operation as that which is described in this paper ought to be useful in a considerable field.

Harley-street, W.

ACUTE AMAUROSIS FOLLOWING INFANTILE CONVULSIONS.[1]

BY HENRY ASHBY, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE MANCHESTER CHILDREN'S HOSPITAL;

AND

SYDNEY STEPHENSON, M.B., C.M., F.R.C.S. EDIN.,
OPHTHALMIC SURGEON TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN, LONDON, ETC.

ONE of the present writers[2] has recorded a number of cases of amaurosis in infants in which the blindness was due to attacks of posterior basal meningitis which had ended in recovery. We propose to bring before the society on this occasion another group of cases of amaurosis in early life which we believe is entirely distinct from the post-meningitis group and owes its origin to severe convulsions. It is not uncommon in the out-patient room to get a history from a mother that her infant or child was left blind for some weeks or longer after having had a severe series of convulsions. We may get such a history when investigating cases of "infantile hemiplegia." The story runs that the child was convulsed for some hours and when he became conscious again he was blind and that his right arm and leg were paralysed. The sight completely returned but not the power in the limbs. In other cases the paralysis has been but slight and the paresis disappeared before the amaurosis. No doubt much caution must be exercised in drawing conclusions from the history given from friends as to the condition of the infant's sight. Such unskilful observers as the parents of out-patients usually are will be likely to confuse "unconsciousness" or "mind-blindness" with loss of sight. Moreover, the blindness spoken of might be due to posterior basal meningitis or to a temporary papillitis. But after putting on one side all sources of error and excluding doubtful cases, there remains a group in which a more or less temporary blindness is "post-eclamptic"—that is, follows as the result of a series of convulsions with coma which remind us of the "status epilepticus" of adults. The amaurosis may be accompanied by aphasia and hemiplegia of a temporary or more lasting type. It may be objected that convulsions do not constitute a "self-standing" disease, but are only accidental complications of many pathological states, and this is no doubt true, but our point is that whatever their origin the convulsions themselves are the actual cause of the amaurosis to which we refer. The explosions or nerve storms may involve the visual cortical centres as well as the Rolandic motor centres, or the speech centre, and the period of discharge be followed by a period of exhaustion. The following cases will illustrate our meaning.

CASE 1.—The patient, aged three years, was admitted to the Manchester Children's Hospital on Dec. 19th, 1902. The history given by the mother was kindly supplemented by Dr. J. B. Cruickshank who attended the child during the acute attack. A paternal uncle had suffered from epilepsy and an infant brother had died in convulsions. The patient had suffered from convulsions a year before; he had also suffered from eczema. Two weeks before admission, when in apparent health and without any assigned cause, he was seized with severe general convulsions which lasted four or five hours. There was drowsiness for several days after the convulsive state was over. The temperature during the "status eclampticus" rose to 103·5° F.; the pupils were at first pin-head in size but later were dilated and sluggish. Examination of the eyes by Dr. Cruickshank showed no optic neuritis or any coarse changes; there was no albumin in the urine. One of the first things the child said when coming round was, "Mummy, draw the blind up," and his repeating this request several times called the attention of the friends to the fact that he could not see (it is interesting to note that the child had clearly pictured memory-image of the window with the blind up and also the state of darkness when the blind was down). There was some paresis of the left arm. On admission it was noted that there was no paresis; the knee-jerks and plantar reflexes were normal, the boy seemed to be completely blind, but the pupils were of the normal size and reacted to light. The pupils contracted well when light was thrown on them with an ophthalmoscopic mirror but the child did not seem to notice the light. They dilated well with atropine. The fundi were normal. His hearing was abnormally acute: he would sit up in bed playing with toy animals which he recognised by touch and chatting to the other children when he heard their voices. He would sing nursery rhymes while playing on a toy piano but often missed the keys as he could not see them. About ten days after admission, when the ward was lighted up at night, he repeated for the first time, "Light, light," and about the same time he was conscious of the light of the taper when brought near his face and when asked to blow it out he tried to do this but usually in the wrong direction. He could recognise a watch if placed in his hands by putting it to his ear but he could not see it. By Jan. 16th it was evident that his sight was returning and he could recognise objects such as books or a watch a couple of yards off. After this there was a rapid improvement and by the 29th he could recognise toys on the other side of the ward and pick up beads and pins. He was clumsy for a while on his legs and he ran against things and knocked his head against chairs for some time after it was certain that he could see. Recovery appeared to take place in both eyes slowly and equally and we could obtain no evidence of hemianopia or that central sight returned before peripheral, but the fact that he knocked his head against the ward furniture when running about was suggestive of his peripheral vision being less acute than the central.

CASE 2.—A boy, aged seven months, was first seen on Dec. 1st, 1897, at the North-Eastern Hospital for Children. He had been wasting for a fortnight, with occasional vomiting and constipated bowels. He had been brought up on the breast and when examined had four teeth. On Jan. 26th, 1898, since the last visit he had had "congestion of the lungs," followed by fits lasting for a fortnight. The child was found to be blind after the fits. There was now weakness of the right arm and leg. There was no optic neuritis and there were no coarse changes in the fundus of the eye. The pupils were equal and active. There was no family history of fits or of lunacy or of epilepsy. On Feb. 23rd the child still appeared to be blind. On March 9th some vomiting still occurred from time to time. The eyes did not follow a light. The pupils were active. There was no rigidity of the right arm and leg, both of which he was able to move slightly. On May 11th the mother was certain that the child was blind. There were slight rigidity of the right arm and weakness of the right leg. The knee-jerk on the right side was exaggerated. The optic discs were thought to be slightly white but the ophthalmoscopic examination was difficult and incomplete It appeared that the child had several fits a week or so before and the last fit was followed by a period of apparent unconsciousness. On

[1] A paper read before the Society for the Study of Disease in Children on March 20th, 1903.

[2] Fleeting Amaurosis in Infants. By Sydney Stephenson, M.B., C.M., Reports of the Society for the Study of Disease in Children, 1902.

June 15th the child moved all his limbs freely and no rigidity could be made out The knee jerks were exaggerated The eyes followed movements of the ophthalmoscopic mirror On Sept 7th the mother stated that about a month previously she noticed that the child looked at things and she was of opinion that he could now see with his right but not with his left eye On Feb 25th, 1903, when the child was nearly *six years of age, the mother stated that the sight had slowly* improved until it became quite good The right arm and leg also recovered He was unable to walk until six months before but now got about nicely by himself The sight was good, the knee jerks wer

good The limbs were o

CASE 3 —A boy, aged

sions about two months before he came under notice and they were followed by a period of unconsciousness which lasted for four days There was intercurrent vomiting Upon recovery he was found to be blind and his right arm and leg "hung as if paralysed ' The sight was stated slowly to have improved, so that when he was seen it was impossible to satisfy oneself that there was any departure from the normal in that respect The pupils were equal and active, the fundi showed no morbid changes The right arm and leg, however, were distinctly weaker and colder than those of the opposite side

CASE 4 —A girl, aged 14 months, had suffered from a cerebral attack some four weeks before she came under notice This was marked by convulsions, vomiting, semi-consciousness, screaming fits, and incontinence of urine and fæces The symptoms persisted for four or five days and then gradually passed away when it was found that the child was perfectly blind The right leg was also weak When *the child was seen she did not follow the flash of the* ophthalmoscopic mirror at all *readily and the vision* of the right was thought to be worse than that of the left eye Her sight, by the way, was stated to be improving The pupils and fundi (examined under chloroform) were normal The case then passed from under observation

CASE 5 —A boy, aged five years, was admitted to the Manchester Children's Hospital on Oct 2nd, 1902, with "infantile hemiplegia" The mother stated that when 18 months old he had a severe attack of whooping cough followed by convulsions He was convulsed for four hours, this was followed by stupor for some days It was then noted that his right arm and leg were paralysed and also the right side of his face He was blind and could not speak His sight gradually returned in the course of a week or two but he did not speak for a month He had a well marked spastic hemiplegia and slight facial paralysis His intelligence was fairly good

Remarks —Nettleship[3] has reported two cases similar to the above and Gay[4] reports four more Both authors, however, relate other cases of amaurosis which are clearly not on all fours with ours If we analyse these 11 cases which include our own and those of the above named authors we find as far as age is concerned that two were between six weeks and two months, two between seven months and eight months, four from 13 months to 18 months, and three from two and a half months to three years In two cases the convulsions occurred during whooping cough and one followed "congestion of the lungs", in eight cases no cause could be assigned In one case the convulsions were only slight, in the rest the attacks were evidently severe, the "status eclampticus" lasting for some hours and unconsciousness or stupor for some days In one case, aged two months the convulsions and stupor lasted for two weeks, the amaurosis which followed was still present when seen at 17 months of age, and there was apparently some optic atrophy as the ' discs were of a light tan shade ' In four of the cases there was no accompanying paralysis In seven (or 63 per cent) there was more or less paralysis, in one of these the paresis of the left arm disappeared in a week or two In four there was a well marked right hemiplegia which lasted for some months and in some of the cases the paralysis seemed likely to be permanent In one case there was a left hemiplegia and in another weakness of the legs The fundi were normal in all but two, one was whiter than normal and in the other the discs were of a light tan shade In all except one there was recovery of sight, in the exceptional case blindness seemed likely to be permanent For the most part the pupils were observed to be normal and active, in others sluggish In one case there was temporary aphasia. In only one have we a note of the urine (Case 1), in this case there was no albuminuria

What were the nature and cause of the convulsive attacks? The history in nearly all of the cases records that the fits were frequent and accompanied by coma or stupor which lasted some hours or days This condition of coma appeared so serious in some instances that death appeared to be imminent In two cases whooping cough seems to have been the exciting cause, in another ' congestion of the lungs," while in other cases no cause could be assigned It is possible that the toxin of pneumonia or influenza may have been the immediate cause in some of the cases, or less likely the convulsions were uræmic This condition of "status eclampticus' which occurs in infants and young children is in some ways remarkable and no doubt does duty on occasion for "brain fever" or "meningitis' from which recovery takes place The post mortem findings in such cases, according to our experience, are disappointing, nothing but a wet brain with venous congestion being found—at least, to the naked eye Probably this condition is much oftener due to reflex irritation rather than to central lesions In those cases which are associated with a hemiplegia which becomes permanent there can be but little doubt that there is a grave organic lesion, such as a thrombosis or hæmorrhage involving part of the Rolandic area or its "hinterland," but whether the lesion is the cause or consequence of the convulsions in any given case must at present be left an open question The stage of coma which is so often prolonged for some time after the convulsions have *ceased may be the result of exhaustion or of the toxin poisoning* and when *consciousness returns the visual centres* are left in an anæsthetic state or the motor speech centre or other motor centres may be left in a temporarily exhausted condition

There is some evidence to show that the visual cortical centres are involved in the epileptic attacks of adults It is well known that visual aura are not uncommon Gowers[5] records that "loss of sight preceded loss of consciousness in 26 cases out of 1000 cases collected by him In one case the loss of sight in minor attacks lasted for an hour and was followed by an hour's sleep ' Gowers concludes that "the phenomena of these aura suggest that there may be both a discharge and an inhibition of the same centre For instance a patient always first saw a flash of light, then sight was lost, and then consciousness " Auditory warnings as well as visual appear to occur in the epileptic attacks of adults, though perhaps not so frequently We are not aware of any loss of hearing following on the fits of infants or children In the night terrors as well as in the rarer "day terrors' of children, conditions which are allied to epilepsy, the frights are occasioned by the involuntary recall of visual memory images, the child sees pursuing wild beasts, rats, or other horrors, but does not appear to hear any sounds Transient hemianopia or at any rate partial blindness, is apt to occur in association with migraine in neurotic subjects A neurotic girl under our observation, who often has severe headaches, frequently complains in these attacks that she cannot see anything situated in the right half of the field of vision In looking at the word "Monday," for instance, she sees "Mon" but not 'day" W Harris[6] has recorded some cases of hemianopia following unilateral convulsions in adults with general paralysis and also following the attacks of migraine He says that "in many cases an epileptic discharge may originate in or near the half vision centre on one side, in some cases proceeding no further beyond producing temporary hemianopia, and in others producing a typical epileptic fit, and again in others giving rise to unilateral convulsions without loss of consciousness ' Dr F J Batten tells us that he has also seen a temporary hemianopia follow an epileptic or convulsive attack in a child

A transient aphasia may also occur in association with a temporary amaurosis following convulsions, as in Case 5 In another case coming under our notice an aphasia which lasted two months followed a convulsive attack but was not associated with any blindness A boy, aged two and a half years, suffering *from whooping cough* was *seized with* convulsions which lasted four hours and when consciousness returned it was found that he could not speak. When seen shortly after he appeared quite well and understood what was said to him, but refused to say a word. He pushed his plate at dinner-time when he wanted more. Two months later he began to say a few words and then quickly became as big a chatterbox as ever. We have already noted the occurrence of a temporary paresis of hemiplegic distribution which is found not infrequently after convulsions, recovery taking place in the course of a few days or weeks. This also follows epileptic attacks as is well known. In infantile convulsions from reflex excitation the spasms are often one-sided or at least more marked on one side than the other and the side which has suffered most is apt to be weak for a while.

[3] Recovery from Amaurosis in Young Infants by E Nettleship F R C S Eng Transactions of the Ophthalmological Society, vol xiv 1894

[4] Acute Cerebral Amaurosis of Infancy by W Gay M D, Royal London Ophthalmic Reports vol xiii, 1893

[5] Epilepsy and other Convulsive Diseases by W R Gowers M D F R S

[6] Hemianopia with special reference to its transient varieties by W Harris M D Brain vol 20 1897

In conclusion we would venture to suggest: 1. That there is a form of amaurosis which occurs in infants or young children which is post-eclamptic, due to anæsthesia of the visual centres. 2. That the convulsions, which may be due to various causes, are apt to be severe and accompanied by coma. 3. That the amaurosis may be associated with aphasia and paresis of hemiplegic distribution; the hemiplegia may be permanent. 4. That the amaurosis is for the most part transient. It is possible that in some instances there is hemianopia.

FOREIGN BODY IN ONE OF THE MAIN DIVISIONS OF THE LEFT BRONCHUS;

ATTEMPTED REMOVAL BY POSTERIOR BRONCHOTOMY THROUGH THE PLEURAL CAVITY.[1]

BY J. GRANT ANDREW, M.B., C.M., F.F.P.S. GLASG.,
ASSISTANT SURGEON TO THE VICTORIA INFIRMARY, GLASGOW.

THE patient, a boy, aged 15 years, was admitted to the Victoria Infirmary, Glasgow, under the care of Mr. A. E. Maylard, on the evening of Dec. 24th, 1902, as an urgent case. He had been amusing himself in bed before going to sleep with a toy squeaker similar to what is placed in india-rubber dolls, when forgetting to remove the whistle from his mouth he fell asleep. He was not long asleep before he was suddenly awakened by a sense of suffocation, for the whistle had entered his windpipe. No amount of coughing and slapping on the back had any effect in dislodging the body and he was hurriedly taken to the infirmary. On his admission it was at once evident that the whistle was lodged somewhere in the windpipe and was probably lying straight across, for with every respiration there was a short shrill inspiratory whistle, followed by a longer expiratory squeak similar to what is got in squeezing a rubber doll but more muffled. The whistle was described as round in shape, with a hole in the centre, a serrated and a smooth edge, and of about the size of a threepenny-piece. Beyond an occasional fit of coughing its presence caused him little discomfort. The house surgeon, Dr. John Paton, examined his larynx with the laryngoscope. He found the cords patent but could not see the squeaker. On the following morning, the 25th, the whistling with respiration was still audible. The larynx was the only part tender to touch and nothing could be felt externally. The respiratory murmur was less marked all over the left lung, and more air seemed to be entering the right than the left lung. Dr. D. O. Macgregor, the superintendent, examined him with the screen but could not then locate the whereabouts of the squeaker. Under an anæsthetic the trachea was opened and Mr. Maylard made an examination of the windpipe and bronchi with long probe and forceps, but with a negative result. He could not be certain that he touched the foreign body at all and he raised the question whether it had not been expelled, perhaps coughed up and swallowed. A tracheotomy tube was inserted. For the next day or two there was little to note except that since the trachea was opened the whistling had ceased, that comparative dulness was now present all over the left lung and more particularly at the base, that the respiratory murmur was lessening and accompanied by moist crepitant râles, and that the pulse, respiration, and temperature were gradually rising. On the 29th his condition assumed a more serious aspect. The expectoration, of a muco-purulent character, was beginning to smell badly, the cough was very troublesome, and the patient's appearance was such as to suggest septic poisoning. The possibility of a commencing gangrene of the lung was considered. Another skiagraph taken by Dr. Macgregor showed the squeaker to be at a point between the fifth and sixth ribs on the left side and three-quarters of an inch outside the left border of the sternum. Mr. Maylard having to go out of town the case came under my care. Before leaving Mr. Maylard mentioned to me that he thought the boy's condition was very serious and that I had his sanction, to do what I thought best. As no improvement was taking place, and now knowing the exact position of the squeaker, I determined to try its extraction. Enlarging the tracheotomy wound I passed a long probe into the bronchus and was quite confident that I felt the squeaker. With a long piece of silver wire bent like a hook I fished for a long time and thought more than once that I had caught it. Whether we were correct in supposing it to be too tightly held by the swollen mucous membrane or not I do not know, at any rate I failed to dislodge it. We then tried inversion, but with no effect. Regarding the outlook as very black if we left the squeaker where it was, perhaps unwarrantably so, I made an attempt to get at it from behind through the posterior mediastinum, removing two inches or so from the third, fourth, fifth, and sixth ribs between the base of the scapula and the vertebral column. On opening the pleural cavity, in which there was some fluid, it was at once seen that some air at least was entering the lung, for with every inspiration it was blown against the opening and with expiration sucked up into the upper third of the chest cavity. To fix the lung sufficiently to examine the root was the difficulty. We partly succeeded by inserting plugs of gauze, but every now and then a violent fit of coughing would supervene which did not facilitate matters. The structures forming the root of the lung could be fairly easily identified, though they seemed all clumped together, and it was only by the finger that one could recognise the more resistant wall of the bronchus By palpation of the bronchus and examination of one suspicious spot with a needle I satisfied myself that the squeaker was not in the main bronchus, but in all probability was in one of its branches and covered by lung tissue, though I did not feel it. We thought it wise at this point to proceed no further and accordingly partly closed the wound, using gauze as a drain.

For a week after the operation the discharge from the wound behind was serous; it then became semi-purulent and ultimately purulent, necessitating the insertion of a tube. The expectoration continued to be profuse, muco-purulent in character, and at first very fœtid. Some sloughy tissue was discharged from the posterior wound, but the amount of discharge, never abundant, gradually lessened. The expectoration diminished, the physical signs cleared up, the patient put on weight, and he was dismissed on March 11th with the wounds healed and in excellent health. The cicatrix behind is with every inspiration drawn slightly inwards; the movement of the scapula towards the vertebral column (the action of the rhomboidei) is less than on the sound side; other movements are free. Before dismissal Dr. Macgregor and myself examined him thoroughly with the "screen," but failed to find any trace of the squeaker. Skiagraphs were also taken but revealed no shadow of the whistle. Naturally the question arises, Where is the squeaker? That it was in the bronchus at the time of the operation is absolutely certain. The skiagraph was taken the night before the exploration and it is hardly possible to believe that it could have been coughed up without the knowledge of the boy, who was intelligent and aware of its presence in the lung, or of the special nurse in charge of the case. That it was not coughed up or discharged through the posterior wound subsequently to the operation I am equally certain; that it might have been coughed up, swallowed, and passed by the rectum is possible—the boy thinks not. For the first week only after the operation were the stools strained.

I bring this case forward, however, principally to raise the question as to the best method of approaching the bronchi. In considering this question it is necessary to start with the assumption that all other measures for extraction have failed and that the case is a desperate one necessitating an extreme measure. Nothing short of this would justify an operative procedure which is undoubtedly performed with great risk. I know that the greater proportion of cases of foreign bodies in the bronchi or lungs get well in time by expulsion, by encapsulation, or otherwise, but [illegible] cases which end fatally chiefl[illegible] In these extreme cases wh[illegible] commencing, or is actually [illegible] body revealed by radiography is in an accessible position—I mean the main bronchus or one of its branches—surely some effort should be made in these cases to extract the body even though it entails an operation such as that attempted in the present case. In the February number of the *Annals of Surgery* for this year there is a very interesting editorial article on "Intramediastinal Bronchotomy and Œsophagotomy," by one of the editors, Lewis Pilcher of Brooklyn. The whole work done in this particular field is reviewed and reference is made to most of the published cases. The method of approaching the bronchus through the anterior mediastinum is first considered and details are given of Ricard's[3] case and of Milton's[4] case. In both of these cases the foreign body was the same, the inner cannula of a tracheotomy tube, and in both the cannula was in the right bronchus. Ricard "resected the upper half of the sternum, uncovered the trachea near its bifurcation and palpated it repeatedly but could not feel the cannula either at the lower part of the trachea or at the beginning of the bronchus." Milton divided the sternum in the median line and drew the two halves apart by strong retractors. He had some difficulty to begin with in exposing the bifurcation of the trachea but succeeded by drawing the trachea upwards. The trachea was opened low down and the cannula was removed. The patient in Ricard's case died from gangrene of the lung and in Milton's from mediastinal sepsis. Pilcher concludes his remarks on the anterior operation thus: "These two cases illustrate well the possibilities, the difficulties, and the dangers of attacks upon the air passages through the anterior mediastinum. ...... The future successful mediastinal tracheotomy will in all probability combine the following steps: (*a*) the sternal resection of Ricard; (*b*) the exposure of the trachea by the pushing back of the pleura and the holding aside by retractors of the great retrosternal vessels; (*c*) the lifting up of the trachea by traction from above through a hook inserted into the old tracheal opening in the neck; (*d*) the incision into the trachea *just above its bifurcation*; (*e*) the exploration of the bronchi through the wound, the detection and the removal of the foreign body; (*f*) the tamponade of the anterior mediastinum, with the external wound left widely open to afford unrestricted exit of wound discharge; (*g*) later secondary suture or healing by granulation as the case may require." The method of approaching the bronchus through the posterior mediastinum is then referred to and the opinion of Quénu[4] quoted as to the best method of approach, based alone upon experiments upon the cadaver. Briefly, the method advised by Quénu is as follows: exposure of the ribs by flap, removal of portions of the third, fourth, fifth, and sixth ribs, and stripping the pleura from the chest wall so as to gain access to the bronchus without opening the pleural cavity. This method is "a further development of the observations made by Quénu and Hartmann[5] with regard to the possibility of exposing the œsophagus through this opening."

---

[1] The case was shown at a meeting of the Pathological and Clinical Society, Glasgow, on April 20th, 1903.

Two unsuccessful cases by Rehn[6] and a successful case by Enderlen[7] are given of œsophagotomy by this route but no case of bronchotomy by this method is quoted nor can I find any record elsewhere. Pilcher concludes his article thus: "From this review of the published cases in which up to the year 1900 efforts had been made to reach the bronchi or œsophagus through the mediastinal spaces, anterior or posterior, there was little to encourage its further practice. Operative procedures which may be successfully carried out upon a cadaver are attended with the greatest of difficulty and danger in the living subject." As Willard,[8] who attempted bronchotomy on dogs, very pointedly remarks: "The aspects of the parts during life and after death are as absolutely different as they can possibly be. A bronchus which after death is easily exposed, and which is reached with the greatest ease, I have seen five minutes previously absolutely enclosed with huge pulsating vessels of twice the size, any one of which, if punctured, would seriously complicate, *if not render the operation absolutely fatal*. The alteration of the parts in life and in dea[illegible] Paget, [illegible] says: [illegible] of our reaching and removing foreign bodies in the bronchi by any direct incision of them. It is true that one might possibly gain access to a bronchus through the posterior mediastinum without opening the pleura, or, at all events, without causing collapse of the lung, but the dangers of hæmorrhage are so great and the uncertainty of the whole procedure so frightful that the operation is hardly ever likely to be practised. And how can the surgeon explore the bronchus or get a hold of the foreign body through a button-hole in the bronchus deep inside the chest? How can he close his incision even if he can make it? And how can he prevent infection of the mediastinum if he leaves it open? These objections may be theoretical, but so is the operation." I make this somewhat lengthy extract because many of the points raised by Mr. Paget bear on the present case and help us to come to a right conclusion as to whether the operation is really a justifiable one or not. There is no reported case, as far as I can find, of deliberate exposure in the living subject of either bronchus through the pleural cavity for the removal of a foreign body. The dangers and difficulties of this method of exposure are without doubt considerable and only the extreme gravity of the case, as before stated, would warrant such a procedure.

Pneumothorax.—The danger of sudden and alarming respiratory embarrassment, if not of actual death, from pneumothorax, or rather from collapse of the lung, has been regarded as sufficient to ban this route. That there was respiratory difficulty in the present case is true, but it was not alarmingly increased when the pleural cavity was opened and extensively opened. Perhaps this was partly due to the fact that the anæsthetist, Dr. D. Lamb, administered oxygen whenever he thought the breathing or colour of the patient demanded it; perhaps the youth of the patient had also something to do with it.

Movement of the lung.—The great difficulty in this case was the constant movement of the lung; it flopped about in the chest cavity like a sail in the wind with a loose sheet. Gauze packing steadied it sufficiently to palpate the bronchus, but, had we felt the foreign body in the bronchus, this movement of the lung would have greatly increased the difficulty of its extraction if it had not prevented its extraction altogether. To overcome this difficulty I believe that the safest and the most satisfactory course would be to remove a portion of another rib and insert one's hand into the pleural cavity. The root of the lung could then be palpated between the forefinger and thumb and the bronchus easily identified by its cartilaginous rings. Should the foreign body be detected this fixation of the root would enable the operator to incise the bronchus and to extract it. I do not think that this is such a[illegible] it would appear; as it was, I had [illegible] the chest cavity. It certainly wou[illegible] in fixing the root, greatly facilitate the examination of the bronchus, and greatly lessen, if not entirely remove, the possibility of injuring ei[illegible] vations of [illegible] The appro[illegible] the surgeon to deal with a gangrenous patch [illegible] incision or otherwise and even to remove the entire lung if necessary.

The conclusions which might be drawn from this case and a consideration of the subject in general are these: 1. A foreign body in the right bronchus not far below the bifurcation of the trachea, which of course defies extraction by other measures, is best got at through the anterior mediastinum, the technique as detailed by Pilcher. The exploration

of the left bronchus through the anterior mediastinum is anatomically impossible. 2. A foreign body in either bronchus well down near the lung can be reached, if other means fail and the nature of the case demands it, through the posterior mediastinum. With the arm hanging over the table a vertical incision midway between the base of the scapula and the vertebral column, and extending from the upper border of the third rib to the lower border of the seventh rib, should be made dividing everything right down to the ribs. A flap incision is a disadvantage as free drainage is advisable. The ribs, third to seventh inclusive, should be divided subperiosteally, and from two inches to two and a half inches removed from each. Median division of the pleura is an advantage as its reflection to each side protects the hand from the cut edge of the ribs. 3 By deliberately opening the pleural cavity and inserting one's hand the root of the lung could be easily manipulated, the bronchus incised, and a foreign body removed with greater certainty and certainly with less danger from hæmorrhage than by stripping the pleura from the chest wall. No attempt should be made to close the opening made in the bronchus. The danger of subsequent sepsis would be much lessened by only partially closing the wound and packing from the bottom.

Remarks by Mr. MAYLARD.—My comparatively short association with the case in its initial stages leaves me little to add to what has already been stated by Dr. Andrew. It had been my unfortunate experience to see two cases of death from gangrene of the lung due to the accidental lodgment of teeth within the bronchi; and the gravity of the symptoms which were beginning to show themselves in the case led me to agree with Dr. Andrew that we were fully justified in employing any measures that would reasonably be expected to lead to the extraction of the foreign body or favour its expulsion. Although the attempt to remove it failed it is not altogether improbable that the manipulation involved in the operation may have had something to do with the subsequent dislodgment. The operation was undertaken, as will be learned from Dr. Andrew's own statement, with the strictest appreciation of the gravity of the symptoms which apparently manifested themselves and the severity of the measure it was proposed to employ. Apart, however, from all considerations connected with the operation as employed for this particular case I am of opinion that it is not without its own teaching in regard to the method of approaching the root of the lung, the bronchi, and œsophagus by the posterior mediastinal route; and quite apart therefore from any intrinsic merits connected with the case itself the operation is one which from its great rarity is worthy of being recorded.

Glasgow.

A CASE OF HÆMATOSALPINX DUE TO TUBAL PREGNANCY COMPLICATED BY TORSION OF THE PEDICLE; OPERATION; RECOVERY.

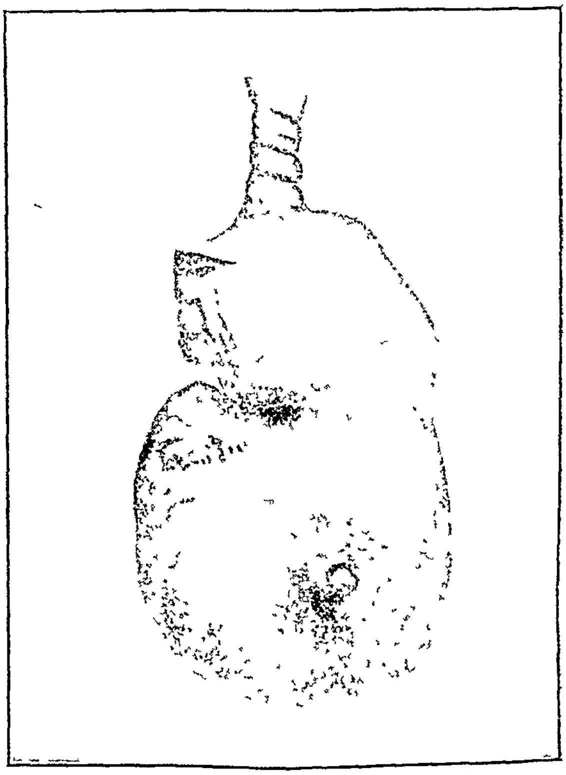
BY FREDERICK J. McCANN, M.D., C.M. EDIN.,
F.R.C.S. ENG., M.R.C.P. LOND.,
PHYSICIAN TO THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, MARYLEBONE-ROAD, N.W.

IN searching through the literature of hæmatosalpinx I have succeeded in finding only one recorded example where torsion of the pedicle complicated a hæmatosalpinx due to tubal fœtation. Martin[1] of Berlin describes a case and gives a drawing of the specimen. The patient, a woman, aged 28 years, had a left-sided ampullary tubal pregnancy at about the second month. The peritoneal cavity contained a large amount of sanious ascites. The tumour was bluish-black in appearance and had two twists in its pedicle. When removed it was found to consist of the left tube and ovary. It had a length of 13 centimetres and a breadth of six centimetres. The Fallopian tube was S-shaped and the ampullary end was dilated to the size of a goose's egg. No fœtus was found, but there was a placenta infiltrated with blood, and there were also blood, hæmatoidin crystals, and fatty detritus. The ovary was the seat of a large hæmatoma and the ovarian tissue was infiltrated with blood. This case presents certain points of resemblance to that recorded in this paper, for in both a fœtus was absent and the torsion of the pedicle was well marked.

In May, 1898, I was asked by my friend, Dr. D. T. Macleod of Sydenham, to see a patient, aged 34 years, who was then suffering from a purulent uterine discharge. Curetting was recommended and performed. No abnormal condition of the appendages was detected at this operation. As a result of the curetting her general health improved and this improvement was maintained. In October, 1900, she was suddenly seized one evening with very acute pain, said to be in the "kidney region," which extended round towards the costal margin in front. Rest and the application of heat for two or three hours relieved this attack. In March, 1901, this pain recurred and the same treatment was again successful. She did not consult a medical man until her third attack, which occurred in the following April. Dr. Macleod was then consulted and he has kindly furnished an account of this and a subsequent attack, which I shall give in his own words:—

> The patient was certainly suffering most acutely and I came to the conclusion that it was due to renal colic I gave a hypodermic of [illegible] and applied warmth. The pain subsided in six or eight hours. and the pain, which was felt well over did not give me any clue to its exact origin—indeed, intercostal neuralgia was even thought of.
>
> The next attack was the final and was accompanied by a rise of temperature (102° F.). It occurred on May 25th, 1901. The pain was distinctly abdominal, not pelvic, occupying the right lumbar region in front. It was most distressing in its acuteness and I felt certain that there was peritonitis (localised) from the general appearance of the patient and the condition of the pulse.

On May 27th Dr. Macleod detected on examination a swelling in the position of the right ovary which was very tender on pressure; and I saw the patient in consultation with him on June 11th. I had the advantage of anæsthesia during my examination. A smooth, rounded, slightly moveable swelling was felt occupying the right posterior quarter of the pelvis. As the patient had never been free from pain since the last attack abdominal section was recommended.



Tubal gestation with twisted pedicle. The figure represents the natural size of the tumour and shows the three twists in the pedicle.

On June 15th, assisted by Dr. Macleod, I opened the abdomen. The anæsthetic (ether) was administered by Mr. Rickard W. Lloyd. After the escape of some ascitic fluid a swelling on the right side of the uterus was exposed. It was bluish black in colour, but at certain points a greenish-yellow shade was noted. The intestines adhered to it. The adhesions were carefully separated and the tumour, with its pedicle, was exposed. Three turns were observed in the pedicle (*vide* illustration). A ligature was applied below the twist and the tumour was removed. The right ovary was not removed. The appendages on the opposite side were normal. The pelvic cavity was washed out with salt solution and the abdominal wall was closed. The patient convalesced rapidly and Dr. Macleod wrote to me that "recovery after operation was uninterrupted and the wound healed by first intention. She has remained absolutely well ever since. The menses are as usual."

---

[1] Die Krankheiten der Eileiter, p. 348.

The illustration above represents the parts removed in their natural size. The dilated tube contained blood clot and dark fluid blood. The tubal wall was infiltrated with blood. Sections made from the wall showed chorionic villi also infiltrated with blood. The tube was closed at its fimbriated extremity. Mr. S. G. Shattock, who kindly examined the specimens, confirmed this opinion. The patient, who had been married for nine years, was sterile. Her menstruation was always regular.

Although the case narrated together with that described by Martin of Berlin are the only two examples of torsion of a hæmatosalpinx due to tubal fœtation which I have been able to find, still such torsion has been described where the hæmatosalpinx was due to other causes. Mr. J. Bland-Sutton[2] describes and figures a specimen of hydrosalpinx with axial rotation. This specimen, which is now preserved in the museum of the Royal College of Surgeons of England, was removed by Mr. Henry Morris. The Fallopian tube between the cyst and the uterus was tightly twisted three and a half times. The tumour was "strongly adherent." The contents were fluid and of a chocolate colour. Here was an example of hæmorrhage from the tubal wall due to torsion of the pedicle rendering the contents chocolate-coloured. This, as is well known, is what occurs when a similar change (torsion) occurs in the pedicle of an ovarian cyst. Hartman and Delbet[3] have also recorded examples of axial rotation of distended tubes. More recently at the Gynæcological Congress held in Vienna von Herff[4] demonstrated a specimen of hæmatosalpinx with twisted pedicle and Kleinhaus[5] has also described and figured a specimen.

No doubt the publication of this case may be the means of bringing forth other cases but at the present time it may be said that torsion of the pedicle is one of the rare complications of hæmatosalpinx due to tubal pregnancy.

Curzon-street, W.

A NOTE ON THE SERUM REACTION OF TUBERCLE,

WITH SPECIAL REFERENCE TO THE INTIMATE NATURE OF AGGLUTINATION REACTIONS GENERALLY AND TO THE THERAPEUTIC INOCULATION OF THE NEW TUBERCULIN.[1]

By A. E. WRIGHT, M.D. DUB.,
PATHOLOGIST TO ST. MARY'S HOSPITAL; LATE PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY.

Technique of the serum reaction.—The difficulties which have stood in the way of the general exploitation of the serum-sedimentation reaction in connexion with tubercle have been technical difficulties associated with the fact that cultures of the tubercle bacillus do not yield uniformly turbid suspensions such as are required for the institution of a sedimentation reaction. Arloing and Courmont showed a way out of this difficulty. They showed that it is possible by a process of careful selection and by frequent agitation of the growing cultures of selected strains of the tubercle bacillus to obtain a uniform bacterial suspension for the purposes of serum sedimentation. Koch introduced an improved technique, the essential feature of which is the grinding up of the tubercle bacilli after previous sterilisation of the cultures under alcohol. The tubercle powder employed—I speak of a specimen kindly placed at my disposal by Professor Dönitz of Berlin—appears under the microscope as an irregular detritus possessing the typical staining reaction of tubercle and containing interspersed here and there an intact bacillus. This powder is employed in the preparation of the test fluid. As much of the powder as will lie on the point of a very small knife blade is taken, is introduced into an agate mortar, and is then triturated with normal salt solution—the solution being supplied drop by drop until about one cubic centimetre has been added. The suspension thus obtained is centrifugalised in a hand centrifuge until the grosser particles have sunk to the bottom, leaving above a clear opalescent fluid. This is the test fluid. When there is mixed and digested for 24 hours with this test fluid a serum which gives the characteristic tuberculous reaction there is thrown down in the fluid a floccular precipitate which aggregates itself into a pellet at the bottom of the containing vessel. The operations of making graduated dilutions of the serum and of mixing with these the test fluid are conveniently undertaken in capillary sedimentation tubes. The technique to be employed is at all points the same as that which I have described in connexion with the typhoid fever and Malta fever reactions.

Question of the intimate nature of the serum reaction.—It will be manifest on consideration that the test fluid which is employed owes its characteristic opalescence to the suspension—probably in a state of semi-solution—in the fluid of a multitude of infinitely fine particles. The essential features of the reaction are possibly in the first instance a process of precipitation, and certainly an agglutination of the finely divided particles, followed by a sedimentation of the flocculated masses. Many convergent lines of work seem to indicate that reactions of this kind play a very large part in the economy of nature and that they are the result of forces derived from the presence of salts in solution. The work of Hardy[2] and Whetham,[3] following upon that of Linder and Picton,[4] showed that the formation of jellies and the coagulation and precipitation of albuminous substances are brought about by forces of this kind. The latter author in particular showed that the forces exerted are progressively more powerful according as the salts in solution are the salts of monads, diads, or triads. Following upon, though not brought into relationship with, the work of Hardy and Whetham came the work of Bordet.[5] This author showed that the bacterial agglomerations formed under the influence of an agglutinating serum are (*a*) resolved into their component elements when these agglomerated masses are transferred to distilled water and (*b*) re-agglutinated by the addition of salt to the water. Lastly, Joly,[6] working in connexion with the problem of the formation of sedimentary rocks and the deposition of silt where river water falls into the sea, has shown that more rapid agglutination and sedimentation of inorganic particles (finely powdered slate) are determined by the presence of salts, in particular by salts of diad and triad elements. It may be noted in this connexion that the clarification of muddy water by alum depends on a practical exploitation of the agglutinating forces derived from a salt of the trivalent element aluminium. These forces are inferred to be electrical forces. The interpretation is justified by the generalisation that electrical forces are generated in watery solutions by the breaking up of the dissolved salts into ions, carrying single, double, or treble charges of positive or negative electricity, according as the ions are monovalent, divalent, or trivalent. The competence of such forces to produce the movements of transposition which are associated with agglutination is established by observations which show that a *solid body suspended in a fluid may be driven out or, as the case may be, drawn in, between electrodes*, according as it offers greater or less resistance to the passage of electricity than the enveloping fluid. A series of simple diagrams—diagrams, let it be remarked, which I owe to suggestions gathered from my friend Professor J. Joly—will serve to bring more clearly before the mind's eye the possible mode of action of [illegible]

In Fig. 1 [illegible] respectively [illegible] vening between these we have a fluid across which the current is conveyed. The lines of force are represented in the diagram by straight lines. In Fig. 2 we have the same two electrodes and the same fluid. But intervening between these we have now a solid object offering to the passage of the current neither more nor less resistance than the fluid medium. The lines of force will in consequence here be exactly as in Fig. 1. In Fig. 3 we have, again, the same two electrodes and the same fluid. But in this case the intervening solid body offers greater resistance to the passage of the electric current. As a result the lines of force will be deflected in the manner shown in the diagram and will exert as they pass round the obstacle a force which will tend to drive the solid body outwards from between the electrodes in the direction indicated by the arrow.

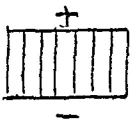

FIG. 2.

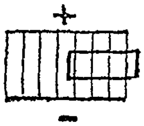

FIG. 3.

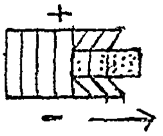
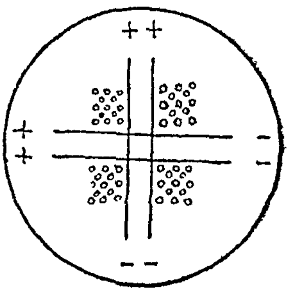


Carrying on the mental image and applying it to the case where electric forces are generated by the ionisation of salts in a fluid we may represent to ourselves the conditions which would obtain in such a medium by some such scheme as that exhibited in Fig. 4. We have here represented by the symbols + and – respectively electric charges carried by Na and Cl ions derived from common salt dissolved in water. Traversing the fluid intervening between these ions are lines of force which would be capable of pushing aside light particles. The displaced particles would, as indicated in the diagram, tend to find a position of rest in the angles between the intersecting lines of force. We may speak of the theory here in question as the "electrotaxis" theory. As set forth above it is, as consideration will show, capable of application in every case where particles offering appreciable resistance to the passage of electric currents are suspended in a salt solution Its application to the case of the serum reaction has not yet emerged. Such a relation, however, emerges if we make the hypothesis that the chemical combination which is known to occur between the agglutinin in the serum and the agglutinable constituent of the bacterial protoplasm is a combination of such a nature as to alter the relation between the conducting power of the suspended particles and the fluid in which they are suspended. We may in fact form a mental picture of the phenomena involved in the serum reaction if we suppose that under the influence of the chemical combination of the agglutinin of the serum with the agglutinable element in the suspended particle the conditions represented in Figs. 3 and 4 are substituted for the condition represented in Fig 2.

FIG. 4.



I would point out that this theory—though it is a theory which I have up to the present been unable to confirm by experiment—may yet be of interest in furnishing a possible explanation of specific serum reactions, and at the same time of the fallacies which are incident to all such reactions and in particular to the serum reaction of tubercle. The theory manifestly indicates that agglutination and sedimentation. since these may be brought about by the agency of salts alone in the case where the suspended particles offer greater resistance to the electric current than the enveloping fluid, are not *per se* of diagnostic value. The physical manifestations here in question are of diagnostic value only when we can infer from their non-occurrence in a control specimen, and from their occurrence in a specimen which has received an addition of serum, that this serum contains a substance which combines with, and induces a physical change in, the bacterial elements in question.

Practical importance of the serum reaction of tubercle.—As in the case of typhoid fever and Malta fever so in the case of tuberculous disease we can if we please exploit for diagnostic uses the elaboration of specific agglutinins in the organism. But we make in any case an unintelligent use of a specific agglutination reaction if we leave out of sight the fact that the presence of agglutinins in the serum is an indication not only of the nature of the bacterial infection but also to some extent an indication of the amount of immunising response which the bacterial invasion has evoked in the system. In particular it is important to note in connexion with the negative result of a serum reaction that it may indicate (*a*) the absence of the particular bacterial invasion which we suspect, (*b*) the purely localised nature of that invasion, and (*c*) the absence of a power of immunising response on the part of the invaded organism. Approaching the consideration of the tuberculous serum reaction from this point of view and bearing in mind in particular the fact that tuberculous infections are for the most part purely localised infections we have little reason to expect to derive much assistance in the diagnosis of tubercle from the indications of the serum-sedimentation reaction. In point of fact, in contrast with what is the case in septicæmic diseases such as typhoid and Malta fever, very little diagnostic importance attaches to the negative result of a serum-sedimentation test in the case of tubercle. Important, on the other hand, in connexion with the serum-sedimentation reaction is the fact that it gives in the case where the patient is being subjected to therapeutic inoculations of tubercle vaccine some indication of the extent to which anti-bacterial substances are being elaborated in the organism. This question may appropriately be introduced by glancing back over the history of Koch's anti-tuberculous inoculations.

Tuberculin inoculations as originally employed and new character with which these have now been tacitly invested.—The method of anti-tuberculous inoculation as originally introduced by Koch was in intention a method of toxi-therapeutics—i.e., a method designed to compass a therapeutic advantage by the agency of degenerative changes produced by the inoculation of toxins. The tubercle toxins were supplied in the form of the original tuberculin, essentially a filtrate from a tubercle culture. The therapeutic object sought was the extrusion and destruction of the invading tubercle bacilli. This goal was to be achieved by the agency of necrotic, degenerative, and inflammatory changes produced by the inoculated toxins in the foci of infection. This method of treatment is now universally recognised to have been wrong in principle. It is not necessary to say anything about its results except that the degeneration and inflammatory change which were produced, as was anticipated, in the foci of infection led more often to a spread of the bacteria than to their extrusion from the system. Of recent years, though the radical change of policy involved has been somewhat glossed over, the anti-tuberculous inoculations have undergone fundamental modification. They have now been divested of their toxi-therapeutical character and have been invested with the character of therapeutical inoculations undertaken with a tubercle vaccine. Hand in hand with this the constitution of the tuberculin has been modified in such a way as to bring it into line with other bacterial vaccines. In the form of the new tuberculin it now contains vaccinating elements derived from the protoplasm of the tubercle bacillus. It is in connexion with these therapeutic inoculations that the tuberculous serum reaction promises, as already indicated above, to be of use. In default of a better method it may serve us for the determination of the patient's capacity of response to the inoculation of tubercle vaccine, and for the proper regulation and interspacing of the successive doses.

I have already elsewhere[7] called attention to the proper regulation and interspacing of the doses in the case of the inoculation of a bacterial vaccine. I may, in view of the fundamental importance of the question, be allowed to recur to it in connexion with the question of tuberculin inoculations where it has a very special importance in consequence of the untoward result which might follow on a reduction of the resisting power of the organism to the tubercle bacillus. The question is capable of being compressed into a nutshell and the subjoined diagrams will serve to bring the issue clearly before the mind's eye. In Fig. 5*a* we have represented in the form of a curve the sequence of events after the inoculation of any bacterial vaccine At *a* we have represented in the form of a straight line the resisting power of the patient anterior to inoculation. Such a base line would represent in the case of an anti-typhoid inoculation the bactericidal power of the patient's blood anterior to inoculation and in the case of an anti staphylococcus inoculation the phagocytic power of the blood as measured by Leishman's method; *in the case of an anti tuberculous inoculation*, such as is here in question, the agglutinating power exerted by the blood on the test fluid which is here in question. At *b* we have represented in the form of the descending limb of the curve a decline in the resisting power of the organism *such as follows*, as I have endeavoured to *show, upon every* inoculation process. I have spoken of this as the "negative phase." At *c* we have the ascending limb in the curve, representing an increased resistance to infection. I have spoken of this as the "positive phase" At *d* we have the final result of a successful inoculation —a higher base line of resistance. In Fig 5*b* we have represented the event of two successive inoculations undertaken with appropriate doses of vaccine and appropriately interspaced. It will be seen that here the negative phase of the second inoculation in the figure comes on the top of the positive phase of the first inoculation, with the result that there is no such sinking away of the resistance below the original base line as occurred after the first inoculation. Let it be noted further that the effect of the two successive inoculations here undertaken is cumulative, and it is cumulative, as we desire it to be, in the direction of the positive phase and of increased resistance to bacterial invasion In Fig. 5*c*, on the other hand, we have represented the event of two successive inoculations inappropriately interspaced. It will be seen that the second inoculation here falls upon the negative phase of the first inoculation, with the result that the resistance of the organism, already reduced by the first inoculation, is still further reduced. I have shown elsewhere that when an undue tax is placed—

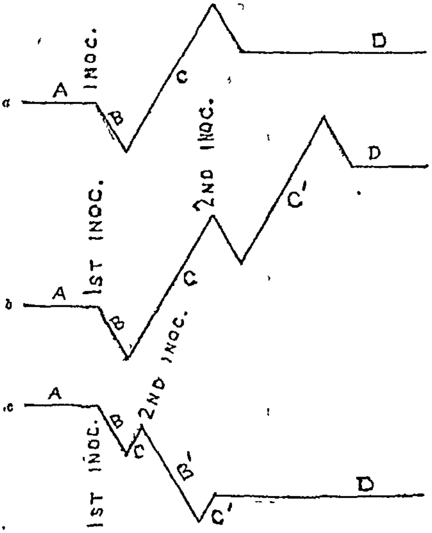
[7] THE LANCET, Sept. 14th, 1901, p. 715, and March 29th, 1902, p. 874.

FIG. 5.



The application of these general principles in connexion with the therapeutic inoculation of Koch's new tuberculin appears to me to be important. It would seem to me that—as is now, I understand, done in Professor Koch's clinic —every patient who is submitted to anti-tuberculous inoculation with the new tuberculin ought to be regularly tested by the serum test to ascertain that he responds to each successive inoculation. When such a system of tests is instituted we may hope to be successful in dealing with localised tuberculous infection by achieving a cumulative positive phase and in maintaining a higher base line of resistance. When *the tests are omitted we may chance to achieve by our* inoculations only a cumulative negative phase.

Lower Seymour-street, W.

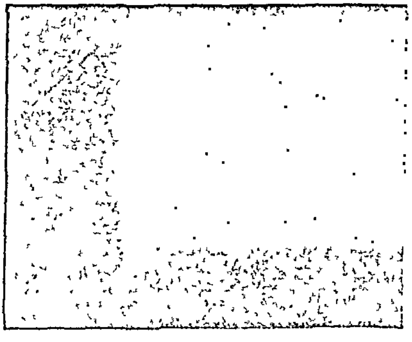
A NOTE ON THE POSITION OF THE HEART IN SOME CASES OF AORTIC ANEURYSM.

BY HUGH WALSHAM, M.D. CANTAB., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN (FORMERLY PATHOLOGIST) TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK.

IT would have been expected *a priori* that aneurysms springing from the arch of the aorta, especially when of large size, would cause considerable displacement of the heart downwards. This is found to be the case and has been insisted upon by most writers on the subject This low position of the heart gives rise to well-marked epigastric pulsation. It is not, however, so much the displacement of the heart downwards as a whole that is important in the diagnosis of aortic aneurysm as the transverse position which the organ takes up in many cases of this disease Indeed, *the heart as seen with the fluorescent screen occupies nearly* a transverse position in the chest in many cases of aneurysm of the aortic arch. This position of the organ tends to raise rather than to lower the apex unless there be considerable hypertrophy of the left ventricle, which is quite the exception in aortic aneurysm. No doubt the heart is pushed into this transverse position by the supra-incumbent weight of the aneurysmal sac I do not think that sufficient stress has been laid on this horizontal position of the heart as a sign of aortic aneurysm. In the absence of other physical signs of aneurysm of the aorta this transverse position of the heart becomes, I think, of great diagnostic value, as the following two cases well illustrate

CASE 1.—A man, aged 56 years, came to the out-patient room of the City of London Hospital for Diseases of the Chest on Jan 19th, 1901, with the following history. He had been in good health up to three months before when he began to suffer with dyspnœa on exertion. He also complained of pain in the back between the shoulders He had never had rheumatism and he denied syphilis. On examination he was found to have well-marked signs of aortic regurgitation. But what especially arrested attention was the fact that although the *heart's impulse was displaced outwards* it was not displaced downwards as we should have expected

FIG. 1.



Aneurysm of aorta with transverse position of the heart.

libitum. In the afternoon he became acutely ill and complained of severe pain in the epigastric and umbilical regions. At the same time he vomited a large amount of bile-stained fluid and assumed the decubitus of acute peritonitis. Dr. Stewart's attention having been drawn to a swelling which had been observed suddenly to develop in the area corresponding to the pain, this was examined and percussion was decidedly tympanitic, but this was only obtainable below as far as the midpoint between the umbilicus and the pubes. Above, Traube's space was considerably increased in area. Movements corresponding to peristaltic waves were visible on inspection and splashing sounds could also be easily elicited by the usual method. The pain at this time was extreme and it was with difficulty that the patient could be touched Owing to his unfavourable reaction to the suppository morphia was contra indicated. Stimulants and frequent injections of strychnine ($\frac{1}{30}$th of a grain) were relied upon, as the heart's action was by this time very much embarrassed. A turpentine enema was also ordered, which brought only temporary relief. The frequent passage of a Jacques catheter was necessary owing to the retention of urine which was secreted in fair amount. The abdomen was still increasing enormously in size, this being most marked in the antero-posterior diameter, and within a short time it was extremely tense. Notwithstanding every means adopted to relieve his condition the patient gradually sank and died in great agony on the 5th.

Necropsy.—At the post-mortem examination, which was held next morning, the stomach was found to be empty and very dilated. Its capacity was 10½ pints. The walls were extremely thin and pale. There was no evidence of stenosis or stricture anywhere. The first part of the duodenum also seemed to be dilated. The heart was fatty with hypertrophy of the left ventricle, while the right side was dilated and filled with dark thrombi. The kidneys were cirrhotic and cystic. There was a large amount of fatty infiltration throughout the body generally. The bladder was flaccid and much dilated. On dissecting the peritoneum from the recto-vesical pouch no trace of deep-seated suppuration could be found and the wound had almost healed. All the other organs looked healthy.

Remarks by Dr. STEWART.—The comparative rarity in medical literature of recorded cases of acute dilatation of the stomach may perhaps be sufficient justification for bringing the details of the above case under the notice of the readers of THE LANCET. From the foregoing account it would appear that the theory of ordinary septic absorption as a cause of the condition will not easily lend itself as an explanation here. Nor is it reasonable to think, as a factor in its causation, of any toxic effect produced by the anæsthetic at the time of operation The condition, however, of "cryptogenetic septicæmia" described by Leube, where no macroscopic appearances could be traced during life or after death, must not be forgotten in elucidation of certain doubtful cases The simultaneous loss of function in the involuntary musculatures of the stomach and bladder would seem to be due to a paresis either from pathological change or functional incompetence in the sympathetic system. After carefully reviewing all the clinical facts I am led to the belief that the case is a similar one to those few cases described by Fagge as "acute paralytic distension" and I think that it should be relegated to this category. It follows, then, that the association with operation may be looked upon purely as an accidental coincidence. For permission to publish the case I am indebted to Dr. F. Pritchard Davies, the superintendent of the asylum.

AT a meeting of the Northern and Midland Division of the Medico-Psychological Association, held at Cheddleton Asylum, Leek, on April 30th, Dr. Menzies being in the chair, Dr. E F. Trevelyan of Leeds exhibited a number of "dry brain" preparations and read a paper on the method of preparing them. He expressed preference for Laskowsky's method. Although there was general shrinkage the convolutions of the brain were not distorted by this method and the colour was well maintained. For demonstration purposes brains prepared in this way were of great value; they could be freely handled, they were elastic and tough, but did not become hard. Dr. Rice showed a remarkably large specimen of an aneurysm of the middle cerebral artery and gave an interesting description of the clinical features of the case.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Hypochlorous Acid as a Disinfectant.—Cretinism in Calves.—Bacteriological Examination of a Case of so-called Rheumatoid Arthritis.—A Note on the Relative Readings given by the Hæmoglobinometers of Fleischl and Haldane.—Renal Dropsy.

A LABORATORY meeting of this society was held on May 5th, Sir JOHN BURDON SANDERSON, the President, being in the chair.

Dr. F. W. ANDREWES and Dr. K. J. P. ORTON made a preliminary communication on Hypochlorous Acid as a Disinfectant.

Dr. C. G. SELIGMANN read a paper on Congenital Cretinism in Calves. He said that in every herd of Dexter Kerry cattle which had been under observation in this country it had been noted that a considerable number of monsters, showing a constant type of deformity, were born. These were, in fact, cretins and the interest of this lay in the facts (1) that they were practically limited to the breed mentioned; (2) that the condition arose in fœtal life; and (3) that it was associated with a diseased condition of the placenta in the parent cow. Of 82 calves born in two herds 19 were monsters of the type under consideration and showed the characteristic short basis cranii, very short limbs, fat pads, &c. The thyroids of all such calves examined showed absence of colloid and the usually malformed or ill-developed vesicles of the gland were choked with more or less spheroidal cells. Extracts of these thyroids when injected intravenously caused no fall of blood pressure. Clinically the pregnancy of a cow about to produce a cretin showed marked deviation from the normal and in the placentæ examined there was extreme myxomatous and œdematous change affecting many of the cotyledons.—Dr. ANDREWES suggested that the condition present in these calves was closely allied to the abnormality known as achondroplasia met with in the human fœtus. He had, however, examined the thyroid gland in cases of this disease and had never been able to discover any abnormality such as had been found in the calves described by Dr. Seligmann.—Mr. S. G. SHATTOCK said that he considered the calves described by Dr. Seligmann were true cretins and resembled exactly the condition produced by the removal of the thyroid gland in young animals If the thyroid gland was removed in the pregnant bitch the bitch underwent no cretinoid changes, but it was found that the thyroid gland of the fœtus became hypertrophied and assumed the function of the maternal thyroid gland. It was difficult to see why a healthy mother should give birth to a cretinoid fœtus when the function of the thyroid gland could be vicariously supplied by the maternal thyroid gland. Two explanations might be offered: firstly, that the disease of the placenta prevented vicarious interchange between mother and fœtus; and secondly, that the herd of cattle which produced these abnormal fœtuses were themselves in a sub-cretinoid condition.—Dr. H. MORLEY FLETCHER asked if a cow which had thrown a cretinoid fœtus would at a following pregnancy again produce a cretinoid calf. He also asked if the thymus gland had been noticed to be large in these calves.—Dr. SELIGMANN, in reply, said that although the condition of the calves might in many respects resemble achondroplasia, yet the absence of colloid substance from the thyroid gland seemed greatly in favour of the view that they were cretinoid. He did not think that there was any evidence to show that the herd of cattle were in a subcretinoid condition. A cow which had thrown a cretinoid fœtus might on a subsequent pregnancy bear a perfectly healthy calf. There was no noticeable enlargement of the thymus gland.

Mr. G. E. GASK read a paper on the Bacteriological Examination of a case of Acute Rheumatoid Arthritis. He said that a woman, aged 29 years, in January, 1903, was delivered of her second child, the labour being apparently normal and not followed by fever. A few days later the right knee-joint became hot, red, and swollen. Subsequently many joints became similarly affected, the patient being confined to bed. The appearance of the patient was one of acute polyarticular rheumatoid arthritis; both knee-joints and *ankle-joints were slightly swollen, painful, and stiff.* Both wrists and most of the carpal and metacarpal joints were in a similar condition. The case resembled those described by Garrod and Hale White. Salicylates had been given with no relief. The bacteriological examination of the synovial fluid of the knee-joint revealed both in films and cultures streptococci which were not to be distinguished from the streptococcus pyogenes. The streptococcus was injected subcutaneously into a mouse and intravenously into a rabbit and proved to be non-virulent. It was not fair to draw conclusions from this isolated case, but it could be fairly said that it resembled clinically in all respects rheumatoid arthritis and that in this particular case the disease was due to streptococci.

Dr. T. J. Horder read a note upon the Relative Readings given by the Hæmoglobinometers of Fleischl and Haldane. A series of ten estimations by different observers was made upon two specimens of defibrinated blood of known strength as regards hæmoglobin. These observations showed firstly an average difference of from 3·65 per cent. (in readings over 50 per cent.) to 4·65 per cent. (in readings below 50 per cent.) between the two instruments, this difference being in favour of Haldane's instrument; secondly, the relative *accuracy of the two instruments amounted to an error of* 1·9 per cent. in the case of Haldane's and of 4·25 per cent. in the case of Fleischl's; and, thirdly, the amount of the personal equation in the use of the two instruments was somewhat less in Haldane's than in Fleischl's.

D[illegible]ions concerning R[illegible]his own observati[illegible], pancreas, and salivary glands, that increased metabolism, as evidenced by increased secretion, invariably caused an increased production of lymph. Dr. Bainbridge supposed that increased metabolism caused the production in the tissues of metabolites having a small molecular weight and probably of a crystalloid nature These diffused into the surrounding lymph spaces, raised the osmotic pressure of the lymph, and so attracted water from the blood; an increased flow of dilute lymph occurred and the blood became more concentrated. It was probable that increased tissue metabolism invariably caused increased lymph formation and if increased metabolism occurred in nephritis it would also cause increased lymph formation which would serve as a factor in the production of œdema. Dr. J Rose Bradford's experiments on the results of removal of large portions of the kidneys showed that the kidneys normally controlled metabolism, especially in the muscles, and that if this control was removed metabolism became excessive. It was probable that a similar loss of control occurred in nephritis. Further, van Noorden had shown that in acute nephritis with œdema urea was present in large excess in the blood and œdema fluid, even though the flow of urine might be considerable and contain a fair quantity of urea. There was therefore considerable evidence that in nephritis the tissue metabolism was increased and in that case it would cause a flow of lymph which would play a part in the production of œdema. *A further point was that the œdema fluid of renal disease* was more dilute than in cardiac disease and that, as shown by Houston, the blood was not hydræmic. Both these facts were characteristic of lymph formed as the result of tissue metabolism.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Ventrofixation of the Uterus.

A meeting of this society was held on April 17th, Dr. J. E. Gemmell (Liverpool), the President, being in the chair.

Dr. W. E. Fothergill (Manchester) showed the Placenta from a case of Acute Hydramnios which terminated with the birth of quadruplets. Labour came on at the thirty-second week. The children all died within 24 hours of birth. Dr. Fothergill also showed a Placenta illustrating marginal insertion of the cord and placenta prævia. The cord was inserted into that part of the margin of the placenta which was prævial, so that unavoidable presentation and inevitable prolapse of the cord occurred. The specimens were discussed by *Dr. D. Lloyd Roberts (Manchester), Dr. J. B.* Hellier (Leeds), and Dr. E. T. Davies (Liverpool), and Dr. Fothergill replied.

Dr. Arnold W. W. Lea (Manchester) showed the specimens from two cases of Tuberculous Disease of the Appendages removed by Abdominal Section. The diagnoses were verified by microscopical examination, although no bacilli were found in the caseous pus.—In the ensuing discussion Dr. Davies raised the question of the route of infection in such cases and held that the alimentary canal was the probable point of entrance.—Dr. Hellier considered that in some cases the semen of a tuberculous husband was the source of infection.—Dr. W. J. Sinclair (Manchester) remarked that the prognosis was especially good in the ascitic form. Flushing the abdomen was to be recommended as it stimulated recovery.—Dr. Lloyd Roberts and the President having spoken, Dr. Lea, in replying, said that the cases had occurred too recently (four months previously) to allow of a positive statement regarding the after history. The disease was primary in the Fallopian tube in both instances.

Dr. Sinclair introduced a discussion on Ventrofixation of the Uterus. The subject, in common with other operations for backward displacements of the uterus, had been of considerable interest for the last ten years or so. He thought that there was a certain amount of levity about the treatment of backward displacements when uncomplicated. Routine treatment was apt to be followed by metritis and all its troubles and it was better to put the patient to bed and gradually to restore the organ to its normal position. The operations for the treatment of backward displacements were grouped as follows:—1. With adhesions existing: (*a*) Schultze's process. Dr. Sinclair had tried it but was not able to believe that anyone could succeed. (*b*) Schücking's operation, which consisted *in freeing adhesions* per vaginam, and by the same route attaching the uterus to the abdominal parietes by a single thread. 2. Alexander's operation (1884) Dr. Sinclair's experience extended to 45 cases, but he was dissatisfied with it so far as the test of pregnancy was *concerned. The objections to it were:—(i.) The round ligament* could not always be found. (ii.) In cases where adhesions were present they prevented the uterus from being drawn forward. In these cases there were also changes in the appendages, so that the symptoms were really due to both cond[illegible] tory [illegible] forwa[illegible] be classified thus: (*a*) pre[illegible]reak down adhesions; and [illegible]my, of which Goldspohn's method was an example. 3. In 1886 Olshausen's first attempt at ventrofixat[illegible] operation had become [illegible] ventrofixation shou[illegible]e devoid of danger; (2) it must be certain and capable of being carried out in every case; (3) it must relieve the symptoms; and (4) it must stand the test of pregnancy and this without giving rise to pain or discomfort; the puerperium must go on normally and at its close the uterus must remain in a condition of anteflexion. The principle that should guide all such operations consisted in safeguarding the fundus uteri and the round ligaments and in insuring *firm* adhesion. No movement between the uterus and the parietes was permissible, otherwise the formation of bands might lead to the occurrence of ileus. A serious test for the operation was prolapsus. In such cases it must be *combined with a posterior colporrhaphy. The operation performed* by Dr. Sinclair was devised by Laroyenne of Lyons and the suture material employed was fine silk. A pessary was placed to act as a splint and the patient was kept in bed for six weeks Dr. Sinclair had done the operation about 100 times in all sorts of women but never in those beyond the menopause as he considered that the suitable cases were those of women in the child-bearing time of life. All cases had stood the test of pregnancy when it occurred, and although there had been instances of abortion and malpresentation these were not in an unusual proportion. He had had no fatality and could not recall any serious rise of temperature or pulse-rate.—The President congratulated the society upon having the discussion introduced in so lucid and able a manner by Dr. Sinclair. His (the President's) experience was limited to 15 cases, of which two were failures owing to defective technique. The others had been quite satisfactory, but as yet none had had to stand the test of pregnancy. Ventrofixation appeared to be the operation of choice in those cases of retroversion associated with adhesions, but he asked if it was an advantage to have as many sutures as those employed in the method used by Dr. Sinclair. The latter, with a record of 100 cases which had withstood the demands of his severe test, had well established the operation in this country.—Dr. Hellier considered the operation of no value in procidentia. He had seen cases so treated where after some time the cervix was found to be procident from the vulva and yet the fundus was still fixed in position against the abdominal wall, the sound passing four or five inches into the uterus. The cases of retroflexion requiring the operation were very few, although the operation gave marked and permanent relief in cases with retroflexed fundus and prolapsed and very tender ovaries where no pessary was of use.—Dr. Lloyd Roberts thought that the operation was not the most scientific that could be devised and that it was not devoid of risk was shown by the reports of fatalities after it had been carried out. He regarded ventrofixation as suitable only in cases uncomplicated by prolapse. The proper treatment for the latter was colporrhaphy.—Mr. S. Rumboll (Leeds) remarked that his experience was limited: in two cases the condition had returned, in two others partial relief had been gained but in these colporrhaphy was required, and in another two the results had been very good. He asked Dr. Sinclair if he had as much faith in the operation in cases of prolapse as in those of retroflexion.—Dr. Davies advocated Alexander's operation which in suitable cases he considered to be an excellent one. He pointed out that Alexander when he first introduced his method stated that it was only applicable to cases in which the uterus was moveable and free from adhesions due to old-standing pelvic peritonitis. When the operation for ventrofixation ran an aseptic course the adhesive reaction between the two surfaces must be so feeble that it was inconceivable that a lasting adhesion would result, and whatever union did occur would in process of time disappear. He did not agree that women who had passed the child-bearing time of life should be excluded from the benefits of the operation.—Mr. E. Stanmore Bishop (Manchester) had had very good results from Alexander's operation, although he preferred to open up the canal and to seize the ligament nearer the internal ring than Alexander advised. When adhesions existed laparotomy was performed, adhesions were freed, and the fundal extremity of the round ligament was united to a point half an inch internal to the internal ring. He believed that the uterus was normally, and should remain after operation, a mobile organ—mobile within limits, which might be fixed, but always mobile.—Dr. J. W. Martin (Sheffield) made some remarks on the method of introducing the sutures, and after Dr. A. C. F. Rabagliati (Bradford) had spoken Dr. Sinclair, in reply, said that he had never prepared the peritoneal surface in any way and had never found sinuses following the use of fine silk. Many of his operations had been performed in cases of backward displacement of old standing with adhesions and those in which the uterus was tender. As to the criterion for the operation, he thought that when an intelligent and experienced member of the profession had treated retroflexion in vain then the case was one for ventrofixation.

Bradford Medico-Chirurgical Society.—A meeting of this society was held on April 21st, Dr. H. J. Campbell, the President, being in the chair.—A discussion on Appendicitis was opened by Mr. F. Farrow and Mr. W. H. Horrocks.—Mr. Farrow defined appendicitis as a peritonitis, local or diffuse, arising in the cæcum or vermiform appendix and septic in character. The most common organism was the bacillus coli communis which, although an inhabitant of the normal intestine, acquired virulent properties in the presence of catarrh of the bowel. The chief causes of the appendicitis were stated to be undigested food in the cæcum or overloading of the bowel with masses of fæces. The irritating effects might be produced either mechanically or chemically by putrefactive products. Mechanical injuries might precipitate an attack in a diseased appendix but they would rarely cause one in a healthy organ. The opinion was expressed that many deaths certified as arising from peritonitis, volvulus, and intussusception would, if investigated, turn out to be due to appendicitis. Mr. Farrow said that cases of appendicitis might roughly be divided into (1) mild cases, (2) severe cases, and (3) surgical cases. Important diagnostic points were (1) severe pain about the umbilicus with pain on pressure in the right iliac region; (2) muscular rigidity on the right side of the abdomen; (3) fever, moderate in degree; (4) vomiting usually; (5) constipation; (6) a swelling on palpation; and (7) a history of previous attacks. Prognosis should always be guarded, as mild cases might rapidly develop a serious aspect. The treatment should be as follows:—1. Rest in bed. Rest to the bowel should be obtained by the administration of small quantities of easily digested food. Rectal feeding might be desirable. 2. Local applications, which were, however, not of much effect either for good or for harm, but leeches to the affected region sometimes relieved pain. 3. In a mild case a purgative might be given at the outset of an attack or an enema might be substituted in severe cases, when opium also should be given. The use of intestinal antiseptics appeared to be rational, especially if the colon was not overloaded with fæces. Operation was necessary in cases of perforation or where pus had distinctly formed, also in cases where attacks were of frequent recurrence.—Mr. Horrocks alluded to the structure and anatomical relations of the appendix and pointed out that they predisposed to a septic inflammation. The peritonitis was at first adhesive and consequently protective in character, and a localised abscess was the most usual result of a perforated appendix. Owing to the various positions in which the appendix might be lying an appendicular abscess might be in the iliac fossa, the right side of the pelvis, the inner side of the ascending colon, or sometimes in the cellular tissue behind the colon. There were no certain means of ascertaining the condition with which they had to deal in cases of appendicitis except by an exploratory incision, and this was attended by the risks of breaking down protective adhesions and converting a localised into a general peritonitis. After detailing the symptoms of an attack and mentioning the various situations in which an abscess might form Mr. Horrocks discussed the general indications for operative interference. He mentioned the following as indications for this interference:—1. A high temperature, from 103° to 104° F., with rapid pulse from the first and with no abatement of the symptoms within 48 hours, together with well-marked abdominal signs and symptoms. 2. When in the course of an attack the symptoms became exaggerated, the temperature either rising continuously or falling suddenly and the pulse increasing in rapidity. 3 When there were definite signs of pus formation. 4 Cases in which there was general peritonitis. If the condition of the patient permitted, removal of the appendix with drainage of the peritoneal cavity would increase his chances of recovery. After the patient had been anæsthetised and before making the incision it was well to ascertain if there was induration at any spot, for if there was the incision should be made over this. If there was no indurated spot the incision should be made rather below McBurney's point If pus was found an attempt might be made to remove the appendix, but the latter should be left if not easily removeable owing to the danger of breaking down adhesions. If pus was not found at once gauze should be packed into the wound and the intestines should be separated till the inflammatory induration surrounding the appendix was found. The cavity should be wiped out and gauze packed into it as a drain. The further from the middle line the abscess was the greater was the chance of recovery. In the rare cases of fulminating appendicitis early removal of the appendix, with flushing and drainage of the peritoneal cavity, offered the only chance. Alluding to recurrent cases Mr. Horrocks advocated removal of the appendix after recovery from a severe attack. He considered that there was an increasing tendency in practice to operate early and to remove the appendix more frequently than was the custom a few years ago.—Dr. C. F. M. Althorp alluded to the frequent association of appendicular disease with disease of the right ovary and spoke of the difficulty and danger of removing the appendix when it was adherent to the iliac vessels.—Dr. S. Johnston believed that early purgation by calomel should be practised in cases of appendicitis.—Mr. J Phillips mentioned a class of cases in which there was an absence of limiting adhesions and in which the peritonitis, though not exactly general, was very extensive. Early operation had been successful in some of these cases which had been under his care.—Mr. J. Basil Hall said that it was useless to try to lay down any definite indication for operation. Each case must be treated on its own merits, the pulse and general condition of the patient being important considerations. In cases of doubt it was better to operate early rather than to wait.—Dr G. T. Beatton also spoke and Mr. Farrow and Mr. Horrocks replied.

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on April 21st, Dr. C. C. Gibbes, the President, being in the chair.—Mr. J. D. E. Mortimer brought forward a communication from Dr. Debout d'Estrées of Contrexéville on the Association of Diabetes with the Uric Acid Diathesis. It was to the effect that Dr. d'Estrées's 35 years' experience at Contrexéville enabled him to state the following conclusions. 1 That 95 per cent. of cases of diabetes were "d'origine arthritique"—a term which might be translated as "due to the uric acid diathesis." 2. That this diabetes of arthritic origin disappeared as uric acid was eliminated by the Contrexéville mineral water treatment 3. That when a patient suffering from diabetes, whether the amount of sugar passed was small (under ·5 per cent.) or large (12 per cent.), did not eliminate uric acid as a result of the Contrexéville course of treatment the results were not so satisfactory, although Dr. d'Estrées claimed that whatever the cause of the diabetes the quantity of sugar was always reduced and the general condition of the patient was improved. Dr. d'Estrées considered that this expulsion of uric acid in the form of microscopic crystals or of gravel, coupled with the disappearance of sugar which commonly occurred towards the end of the course, although no special regimen might have been adopted, was a proof of the community of origin of gout and diabetes which had been already strongly urged by Marchal de Calvi and other French physicians. He did not insist, however, that that community of origin was absolute in all cases of diabetes. Notes of 100 cases were appended.—A discussion followed, when the opinion was generally expressed that whilst Dr. d'Estrées's conclusions were no doubt correct as regarded the class of patients, many of whom might be expected to suffer from "gouty" or "alimentary glycosuria," who frequented Contrexéville, they could hardly be regarded as of wider application —Mr. C. E. Wallis read a paper on Such Dental Information as was of value to the Medical Practitioner. He gave a *résumé* of the common dental affections which were met with, making special remarks on the subject of the sterilisation and hygiene of the mouth. Specimens were shown of dental erosion, excessive deposit of salivary calculus, &c., and a demonstration was given of the latest methods of conservative dentistry with models and specimens of dental crowns, bridges, and plateless dentures, the various advantages and disadvantages of each being explained and discussed. Mr. Wallis pointed out that unless every precaution was taken to sterilise roots on which crowns and bridges were to be placed they were doomed to failure; that when bridges were applied representing several teeth it was necessary that the roots on which the abutments were placed should be absolutely aseptic and possess a living periodontal membrane, and at the same time that they should not be subjected to a mechanical strain greater than they could bear.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held on April 22nd, Dr. E. Symes-Thompson, the President, being in the chair.—Dr. Arthur P. Luff, in reopening the discussion previously introduced by Dr. F. A. de T. Mouillot (Harrogate) on the Dietetic Factor in Health-Resort Treatment, read a paper which was published in THE LANCET of May 2nd, p 1224 —Mr. William Armstrong (Buxton) said that in spa dietary three factors had to be taken into consideration—namely, (1) the precautions necessitated by the special action of the waters of the resort; (2) certain general dietetic principles; and (3) the special necessities of the individual patient. He agreed with Dr. Mouillot's views that the rapid metabolic changes occurring during treatment by baths and waters made it desirable to give more butcher's meat than in ordinary daily life; but he considered that in order to avoid ill-effects from this course it was desirable to cut down as far as possible the starchy and saccharine elements of food, this being specially necessary when the waters depended for their efficacy upon gaseous constituents. In dieting the gouty a definite distinction should be made between those who suffered from a plus formation of uric acid and those who showed a minus excretion and also between those who were too stout and those who were too thin. In rheumatism the tendency should be towards a vegetarian dietary. In rheumatoid arthritis, on the other hand, much red meat should be given, and the dietary generally should be as generous as the patient's digestion permitted —Dr. Neville Williams (Harrogate) said that a more varied diet could be taken with the sulphur waters than with the chalybeate waters. As a general rule mutton, poultry, white fish, and farinaceous foods in moderation could be taken. Vegetables of the cabbage tribe, rhubarb, and most fruits were to be avoided.—Dr. Blaker said that from personal experience he considered that red meats increased the quantity of uric acid All vegetables (potatoes excepted) grown in the sun and air were preferable to those grown under ground. Fruit often disagreed with patients taking iron tonics; dry cider, lemon drinks, moselle, and some ports suited gouty and rheumatic subjects.—Mr. W. Bowen Davies (Llandrindod Wells) considered that the British public would not consent to the restrictions in their own country which they consented to abroad. As a drink cider in his experience was bad in lithiasis, but he found a dry perry the very best drink in gout —Dr John Braithwaite (Buxton) said that the difficulty to him seemed to be in getting hotels and similar establishments to prepare a simple menu —Dr. R. Fortescue Fox, Dr. C. W. Buckley (Buxton), and Dr. W. V. Snow (Bournemouth) also took part in the discussion.

ULSTER MEDICAL SOCIETY.—A meeting of this society was held on April 23rd.—Dr. Robert McDowell read notes of a case of Puerperal Eclampsia in a primipara who was seized with convulsions in the seventh month of gestation. She was treated with purgatives, diaphoretics, the hot pack, morphia, chloroform, venesection, and saline transfusion, but as there was no improvement and as she had passed through 13 convulsions, it was decided to induce labour, which was done by Professor J. W. Byers with Bossi's dilator. This was carried out under chloroform, and the cervix, which only admitted the index-finger when the dilator was introduced, was in less than half an hour so expanded that forceps could be applied and the delivery of the child completed. The patient made a good recovery —Dr. J. J. Austin read a paper on the Prevention and Treatment of Puerperal Eclampsia. He urged the importance of keeping as much supervision as possible over patients especially during the last two or three months of gestation, as when they were treated in the pre-eclamptic stage eclampsia could be rendered as preventable a complication as post-partum hæmorrhage or sepsis. In the treatment of eclampsia he recommended venesection if the face was flushed and the pulse was full, the injection of saline solution, and the subcutaneous injection of morphia with induction of labour if these measures failed. He suggested that when delivery had been carried out without previous venesection the good results frequently following delivery might be largely attributable to the loss of blood occurring at the birth and not to the withdrawal of the fœtus, since the fits often ceased after venesection without delivery —Professor Byers showed and explained the method of use of Bossi's dilator which had been successful in Dr. McDowell's case He thought that it was a most useful addition to the obstetric armamentarium and that many, if not the great majority of, cases of eclampsia could be prevented by careful prophylactic treatment.—Dr. H. O'Neill, Dr. R. W. Leslie, and Dr. J. Lynass also spoke —Mr Dryden Stead, Dr. A. Fullerton, and Mr. R. Campbell showed various cases and specimens.

SOUTHPORT MEDICAL SOCIETY.—A meeting of this society was held on April 29th, Dr. F. J. Baildon, the President, being in the chair.—Dr. E S. Yonge described two [illegible] Larynx on which he had [illegible] dry hoarseness in a patie[illegible]oss of motility and sluggish movements in the vocal cord on one side, were very suspicious symptoms. The operation of thyrotomy with immediate closure of the wound was advocated, an important point being the application of cocaine to the larynx during operation.—Mr. S. B Fenn read notes of a case of Malarial Fever complicating the puerperium and simulating septic infection.—Dr. William Carter of Liverpool read a paper entitled "Some Clinical Reports and the Lessons they Teach." The value of the following procedures amongst others was insisted upon: (1) antiseptic nasal douching in persistent feverishness; (2) slow dilatation in stricture of the cardiac orifice of the stomach; (3) the removal of the sources of irritation in stricture of the bowel from cancer, &c.; (4) counter-irritation in hypertrophic cirrhosis of the liver; and (5) innunction of animal fats—e.g., bacon fat—in wasting diseases.

ERRATUM.—In the report of the meeting of the Society for the Study of Disease in Children in THE LANCET of May 2nd, p. 1240, the words "it did not come" in line 13 should be *it came.*

Reviews and Notices of Books.

Encyclopædia Medica. Under the general editorship of D. CHALMERS WATSON, M.B., F.R.C.P. Edin. Vol. XII., Syphilis to Typhus Fever. Edinburgh: William Green and Sons. 1902. Pp. 528. Price 20*s.* net per volume.

THIS volume contains so many excellent articles that it is difficult to select those which deserve special mention. It is a matter for congratulation that the editor has been able to secure such valuable contributions and as space permits us only to refer to a few of them the omission of others does not imply that they are any less praiseworthy.

The article on Syphilis is by Mr. D'Arcy Power, assistant surgeon to St. Bartholomew's Hospital. After a brief historical review, Mr. Power proceeds to discuss the distribution of the disease, its general pathology, modes of infection, and classification; then follows a detailed account of the symptoms and treatment of the various forms. Mr. Power's manner of writing at once attracts attention and he has succeeded in compressing a vast amount of information into the 44 pages which this article occupies. The remarks on Syphilis in Children are particularly worthy of attention.

The subject of Tabes Dorsalis is admirably considered by Dr. F. W. Mott, F.R.S., director of the London County Asylum, Claybury. He naturally lays great stress on syphilis as an etiological factor and states that "it is the opinion of many authorities that if there were no syphilis there would be no tabes." His own views evidently go far to support this proposition, for he says: "According to my observations, by far the most important, if not the essential, factor is syphilis." Another factor, however, is undoubtedly necessary for the production of tabes dorsalis, and that, Dr. Mott maintains, is nervous instability, the product of civilisation. The section dealing with symptomatology contains a full and lucid description of the clinical phenomena occurring in connexion with this disease. Dr. Mott claims that the most important symptom undoubtedly is the Argyll-Robertson pupil, for in no other disease except general paralysis does this sign exist; he is strongly of opinion that this fact can be upheld and believes that the existence of this symptom alone would justify a practitioner in saying that the patient was a candidate for either tabes dorsalis or general paralysis, and adds: "This is the strongest argument in favour of the unity of these two diseases and of their syphilitic origin."

Notice must be taken of the article on Teeth by Mr. G. W. Watson, lecturer on dental surgery and pathology, Edinburgh Dental Hospital. An interesting survey is given of the comparative anatomy of the teeth and then the genesis of the teeth is carefully considered. The chief morbid conditions affecting the teeth are well dealt with, such as dental caries, diseases of the pulp, and alveolar abscess. The mechanical operations connected with dentistry are also described. An interesting section is that headed "Oral Sepsis and General Bacteriology of the Mouth"; due credit is given to Professor Miller of Berlin for his researches on the micro-organisms found in the oral cavity.

Under the heading "Therapeutics" there are three separate articles: Physical Therapeutics, by Mr. Ernst Flodin (Sweden and Edinburgh); Serum Therapy, by Dr. William Murrell, physician to the Westminster Hospital; and Health Resorts, by Dr. Edmund Hobhouse of Brighton. Considerable space has been devoted to the consideration of Physical Therapeutics. As is pointed out in some editorial remarks which precede this article, the words "massage" and "masseur" have come to bear, in this country at least, a somewhat contemptuous meaning. Uneducated persons have been in times past largely employed to carry out the instructions of qualified practitioners. Fortunately this defect has now been to a large extent remedied; the numerous benefits to be obtained by scientifically applied manipulations are only just beginning to be appreciated by the medical faculty in Great Britain and doubtless much harm has been done by irresponsible persons claiming to "cure" patients without having recourse to genuine medical advice. Mr. Flodin's contribution occupies 57 pages and gives a very full account of the various exercises which may be practised when applying "physical therapeutics"; it also recounts several illustrative cases. The value of the article is increased by the reproductions of numerous photographs depicting the movements which are employed.

There are two articles on the Thyroid Gland and its Diseases. The medical aspect is considered by Dr. G. R. Murray, physician to the Royal Infirmary, Newcastle-on-Tyne, and the surgical aspect by Mr. Frederick Page, professor of surgery in the University of Durham. Both contributions are well written and contain the most modern views on their respective subjects.

In an article on Tuberculosis Dr. Theodore Shennan, senior pathologist to the Royal Infirmary, Edinburgh, discusses in a most able manner the relationship of human and bovine tuberculosis. The views of Professor Koch are fully set forth, but Dr. Shennan comes to the conclusion that the milk of tuberculous cows can cause the disease, though, as a rule, only in weakly individuals whose resistance is greatly lowered, and, secondly, that such milk is dangerous only when the bacilli are present in great numbers or "when it is ingested for a length of time."

There are many other articles to which we should have liked to refer had space permitted; we can, however, only mention some of them: Tumours, by Mr. J. Bland-Sutton; Typhoid Fever, by Dr. S. P. Phillips; Toxicology, by Dr. J. Dixon Mann; and Dangerous Trades, by Dr. Thomas Oliver. This volume fully maintains the prestige established by its predecessors.

Portfolio of Dermochromes. By Professor JACOBI of Freiburg im Breisgau. English adaptation of Text by J. J. PRINGLE, M.B. Edin., F.R.C.P. Lond., Physician to the Department for Diseases of the Skin at the Middlesex Hospital, London. London: Rebman, Limited. 1903. Parts I. and II. 42 Plates. Price, 4 parts, £2 10*s.*

THESE are the first two parts of a new atlas of diseases of the skin which has been arranged by Professor Jacobi and the text has been translated and adapted for the English edition by Dr. J. J. Pringle. The atlas is intended chiefly for those members of the medical profession who are in general practice, and in this respect it differs from most of the numerous atlases of dermatology, which are intended mainly for those who have a special knowledge of diseases of the skin; and therefore the atlas before us concerns itself with the commoner manifestations of cutaneous disorders and not with those rare diseases which are only of interest to professed dermatologists. In no other class of diseases are coloured illustrations so important as in affections of the skin and though many treatises on the subject exist, yet it is difficult to name an atlas suitable for those who are not specialists. We think that the work before us admirably supplies this want, if we may judge of the whole by the parts already received The illustrations for the most part are taken from models in the Breslau clinic and they have been reproduced in colours by a new four-colour process called citochromy This method was invented by Dr Albert of Munich and is very successful in nearly every case in reproducing the exact tints of the original They are the happiest results which we have seen of any photo mechanical process of colour-printing In these two parts there are 42 plates, but nearly every plate has two illustrations on it and some have three, so that there are 90 illustrations in all It is difficult to imagine a more useful atlas for those in general practice The text is in no way intended to take the place of the ordinary systematic treatises on dermatology and therefore it has been condensed as much as possible without the omission of essential facts The English translation is very satisfactory and altogether we can recommend this book Dr Pringle has in one place put a footnote which records the fact that the text does not quite coincide with his own views and there is one other passage which should be amended In the description of variola the author, as pointed out by Dr C Killick Millard in THE LANCET of April 25th, p 1197, does not recognise that variola may occur in an unmodified form even though the patient has been vaccinated Of course this is rare, but the statement in the text is far too absolute and should be altered in a second edition The plates may be purchased loose in portfolios or they may be obtained bound in various styles for a few shillings extra

A Text book of Anatomy By American Authors Edited by FREDERIC HENRY GERRISH, M D Second edition, revised and enlarged With 1003 engravings in black and colours London Henry Kimpton Pp 944 Price 32*s* net

AS set forth in the preface, the aim of the editor of this system of anatomy has been to produce a systematic work of convenient size for the student of medicine For this purpose essential facts only have been presented and considerable effort has been made to 'simplify descriptions which experience has shown commonly cause difficulties to students The book throughout bears evidence of this attempt at simplification and abridgement and, although in size it is almost equal to the text-books in common use in this country, the impression left on the reader's mind, whatever section he consults, is that of a certain incompleteness and a lack of that scientific precision which constitutes the charm of a well written text-book on an exact science. There are many points in the system, however, which are worthy of commendation Much care has everywhere been taken to illustrate the meaning of the anatomical terms which are used and quite early in the volume a series of paragraphs is devoted to the names and delimitations of superficial parts of the body These sections should prove very useful to the student commencing the subject The book is arranged on the usual lines but with the briefest of embryological introductions A special short section is devoted to fasciæ and bursæ which is an advantage, as to get a clear idea of these structures from the ordinary text book necessitates a laborious process calling for a frequent reference to the index Relational Anatomy is the heading of a section which presents some novel features It consists of three sub divisions, under the headings of Plane Sections, Surface Anatomy, and Normal Skiagraphs The pictures are here mostly left to tell their own tale, so that this section is virtually an atlas to be used in connexion with the other parts of the book and is not strictly comparable with regional or topographical anatomy as usually understood

The pictorial and diagrammatic illustrations are a striking feature of the book and give it quite a character of its own It is true that many of the illustrations are old friends which have already appeared in Testut's "Anatomy" and Kocher's "Surgery," but there are others which are both new and instructive A series of diagrams by the editor in which the areas of attachment and actual outlines of the muscles are superposed in red on the skeleton is a novel and useful feature The book contains, too, a particularly good series of plane sections in outline with the names of the structures, as far as possible, engraved directly on them Most of these are placed in the section on Relational Anatomy but others are found in the section on the Vascular System At the risk of repetition it would have been well to have depicted them again in the former situation to make the series locally complete Surface anatomy is illustrated by a series of reproductions of photographs with outline keys, such as are usually met with in atlases of artistic anatomy The normal skiagrams are not the best that we have seen, they were probably prepared in the earlier days of skiagraphy

We are inclined to question the utility of the section on Practical Anatomy It is merely a tabular dissection guide and cannot with advantage replace a proper dissection manual

JOURNALS AND MAGAZINES

Journal of Anatomy and Physiology Conducted by Sir WILLIAM TURNER, K C B, F R S, D J CUNNINGHAM, M D, F R S, G S HUNTINGTON, M D, A. MACALISTER, M D, F R S, and J G M'KENDRICK, M D, F R S Vol XXXVI New Series, Vol XVII, Part 3 London. Charles Griffin April, 1903 Pp 92. Price 6*s* —The articles contained in this part are —1 On the Development and Homology of the Mammalian Cerebellar Fissures, by O Charnock Bradley, M B Edin, professor of anatomy, Royal Veterinary College, Edinburgh 2. Observations on the Relations of the Deeper Parts of the Brain to the Surface, by Johnson Symington, M D Edin, professor of anatomy, Queen's College, Belfast, with six plates 3 Peculiar Malformation of the Tricuspid Valve of the Heart, by T Wardrop Griffith, M D Aberd, professor of anatomy at the Yorkshire College; with a plate 4 Note on a Second Example of Division of the Cavity of the *Left Auricle into two Compartments by a Fibrous Band*, by T Wardrop Griffith, M D Aberd 5 The Cerebrum of a Microcephalic Idiot, by N C Macnamara, F R C S Eng, and R H Burne, anatomical assistant in the Museum of the Royal College of Surgeons of England The posterior lobes of the cerebrum of this brain only very partially covered the cerebellum, the insula was a mere nodule, and the orbital and frontal opercula were wanting Some good reproductions of photographs accompany this article. 6 A Description of Some Anomalies in Nerves arising from the Lumbar Plexus of a Fœtus and of the Bilaminar Musculus Pectineus found in the same Fœtus, with a Study of the Variations and Relation to Nerve supply in Man *and some other* Mammals, by Edward B Jameson M B, Ch B Edin 7 Complete Absence of the Superficial Flexors of the Thumb and Concurrent Muscular Anomalies, by H S Hall, B A. Cantab, with a plate showing a *dissection of the parts* 8 A Method of obtaining Uniplanar Sections with the Ordinary Rocking Microtome, by W Sampson Handley, M S Lond 9 Archæologia Anatomica (anonymous) The term "hilum' is here considered and it is shown to be a good and ancient classical word and one that should be used instead of hilus 10 Thirteenth Report on Recent Teratological Literature by Bertram C A. Windle, M D Dub, F R S. 11 Proceedings of the Anatomical Society of Great Britain and Ireland, January, 1903.

The Cornhill —The May number of this magazine has an interesting article upon Liebig who, the writer says, ' is known to most of us only as the inventor of a method of preparing 'extract of meat.'" We hope that "most of us" does not include the members of the medical profession, for Liebig was, quite apart from his studies in foodstuffs, a most eminent chemist. He did an immense amount of work in organic chemistry and applied chemistry to agriculture and to physiology in a manner that created quite a revolution in the study of the science. Other notable articles are a cheery account of life on board the *Britannia* and a charming paper upon Bird-nesting and Bird-nesters.

HOSPITAL MAGAZINES.

St. Bartholomew's Hospital Journal for March contains the concluding portion of a paper by Mr. E W. G. Masterman on the Cholera Epidemic of Last Autumn in Palestine. This is one of those records of first-hand experience that medical men like to read: it teaches us to understand the problem of disease in novel environments. "Paterfamilias" writes a letter to the effect that much valuable instruction is lost by teaching children nursery rhymes which are quite nonsensical. For the children of medical men he suggests that the old rhymes might be altered. From among the examples which he gives we take the following :—

"Sing a song of sickness, yellow in the eye,
Four-and-twenty gall-stones choledecto-my!
When the wound was opened, the bile began to flow;
When the deuce it's going to stop the doctor doesn't know!"

And again :—

"Three blind boils!
See how they run!
They all ran, after the farmer's wife
Had cut off their heads with a septic knife;
You never saw such a mess in your life
As three blind boils."

Charing Cross Hospital Gazette for March, which celebrates its fifth volume by appearing in a new cover, contains as its *pièce de résistance* a report of a lecture on X Rays and Localisation by Mr. James Mackenzie Davidson.

St. George's Hospital Gazette for March contains a readable note by Dr. Robert Barnes on Sea Salt, with special reference to the Mediterranean. Mr. B. N. Tess deals with Symptomatic Parotitis. In connexion with this subject the editor calls to mind the objection to the term "parotitis" raised by a celebrated member of St. George's consulting staff: "Parotitis! Parotitis! I never heard that the patient had a Parot." "No doubt, parotiditis is more correct etymologically," says the editor, "but the briefer form parotitis at any rate has the sanction of common-sense."

King's College Review.—The March number of this magazine is not confined to the medical side of King's College, but medical matters are dealt with in a fair proportion of its pages. From an instructive history of pathology we extract a nursery rhyme which would appeal to "Paterfamilias" whose letter to the editor of the *St. Bartholomew's Hospital Journal* we have already referred to :—

"Sing a song of sepsis,
Pockets full of pus;
Half a million cocci;
Patient wuss and wuss.

"When the wound was opened
How the surgeon sings—
'Nasty bad condition
To occur at King's.'"

The London Hospital Gazette for March, a good issue, contains a clinical supplement devoted to Dementia Paralytica, whilst the *Gazette* itself is filled with reports relating to hospital matters interspersed with papers of a lighter nature. "Geneva," being the impressions of a tourist with a short history of the city illustrated with reproductions of photographs, is a readable article.

St. Mary's Hospital Gazette for April has for its chief feature a paper by Mr. H. S. Collier on Errors of Ancient Surgery.

St. Thomas's Hospital Gazette.—The March number opens with the report of an address delivered before the Medical and Physical Society of the hospital by Staff-Surgeon G. Walsh, R N., in February last. After detailing the advantages of life in the Royal Navy, Staff-Surgeon Walsh says in reference to the disadvantages: "Life in any calling is not a bed of roses and you will have to put up with many rubs. I believe that they are no worse—and do not occur so often—than they are in civil life, and you will have to learn to take the rough with the smooth."

ERRATUM.—In our review of "Human Personality and its Survival of Bodily Death" which appeared in THE LANCET of May 2nd, p. 1241, there appeared, about 20 lines from the bottom of column 2, the following sentence: "It possesses a very high degree of solid value precisely as a work of analytical psychology, as an exploration of that subliminal region of the mind. This region is below the usual level of consciousness in which ...... arise." The sentence should have read: "It possesses a very high degree of solid value precisely as a work of analytical psychology, an exploration of that subliminal region of the mind below the usual level of consciousness in which ...... arise."

Looking Back.

FOREIGN DEPARTMENT.

ANALYSIS OF FOREIGN MEDICAL JOURNALS.

ARCHIVES GENERALES —MARCH.

Case of Fracture of the Clavicle, and subsequent ossific Union in a Fœtus.

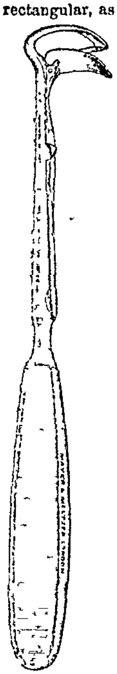
The following case of fracture of the clavicle, read at a late Sitting of the Royal Academy, by a M. Devergie, is a very curious one, and serves to show that the doctrine which has been so long current respecting the impossibility of ossific union being effected, in the case of fracture of a fœtal bone, is incorrect. It has been said, that if, by any accident even in delivery, the bone of either extremity should be broken, that it will not be again united by an ossific union. For this opinion we have never heard any good reasons; and the fact recorded by M.D. refutes it altogether.

A woman in the sixth month of pregnancy, received a violent blow on the abdomen, by falling from a high chair against the corner of a table. The pain which succeeded to this accident was very severe, and continued so for some time. It gradually diminished, and, at the end of the proper time, she was delivered of a very fine child, which was discovered to have a very large tumour in the region of the left clavicle. The child died on the eighth day after its birth, from what cause is not named; and on a careful examination of this tumour, the clavicle was found broken, and one of the fractured portions had projected over the other. They were united by a large and solid callus, which formed the principal bulk of the tumour. The preparation is safely deposited in the Anatomical Museum of the Hospital of Val-de-Grace, and has been examined by a great number of practitioners. The circumstances of the case appear to justify the supposition that the fracture was produced by the violent blow received on the abdomen.

HOSPITAL FOR EPILEPSY AND PARALYSIS.—Princess Louise, Duchess of Argyll, has signified her intention of performing the opening ceremony in connexion with the new Hospital for Epilepsy and Paralysis, Maida-vale, W., on June 13th. We are requested to state that applications for tickets of admission should reach the secretary not later than May 13th

New Inventions.

THE SPRING-GRIP CURETTE FOR THE REMOVAL OF ADENOIDS.



THE blade of the curette is straight and the fenestra rectangular, as shown in the illustration, the cutting portion of the blade being at right angles to the shaft. Up to this point it is practically a Beekmann's curette. To the shaft is fitted, by means of a detachable joint, a long spring, to the terminal end of which is hinged a thin plate which fits accurately into the fenestra of the curette on three sides, but with its anterior limit in contact with the bevelled surface of the blade at about one-sixteenth of an inch from the cutting edge. As the curette is pressed on the growth the plate is forced open by the pressure of the growth on the under surface of the plate. The curette travelling backwards and downwards, the growth passes between the blade of the curette and the edge of the plate. On withdrawing the curette the grip on the growth between the plate and the blade is sufficient to extract the growth by its inferior margin. Its advantages over the cage are as follows: (1) it admits of the presence of the guiding forefinger in the post-nasal space as it takes no more room than the open curette and there is therefore no necessity to have a view of the pharynx, so that there is a slight saving of time which is of advantage when operating under gas; (2) the curette cuts cleaner, as the edge does not get blocked by the retention of the growth in its vicinity; (3) it does not leave the growth hanging in the pharynx, as is sometimes the case with the cage; (4) it removes the growth in a single piece if the stroke is carried through at an even depth and the growth is continuous in structure, never dropping it out if the curette is removed with care from the pharynx; and (5) the time taken in removing the growth from the curette is less than that taken in changing the instrument for another one. I am indebted to Messrs. Mayer and Meltzer of Great Portland-street, London, W., for the care they have taken in carrying out the design.

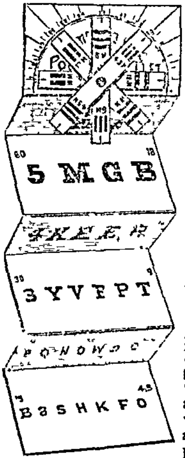
MACKAY MACDONALD M.B., B C Cantab.,
Senior Clinical Assistant, Throat Department,
Harley street, W. King's College Hospital.

IMPROVEMENTS IN HANSOMS.

IN THE LANCET of April 18th, p. 1119, we discussed under the heading "The Objections to the Hansom," the various faults to be found in "the gondola of London" and at the same time we expressed our astonishment that no light, comfortable, four-wheeled open vehicles were to be found in London. We now learn that a consignment of small victorias is coming over from Paris, a fact we are very pleased to learn, and we can only say that we wish them fine weather. But with regard to the hansom there has been brought to our notice a new form of hansom which certainly is free from most of the faults to which we took objection as existing in the present style. The cab in question is called the Alington cab and instead of the ordinary doors and guillotine window possesses semicircular doors, with windows in them which move up and down in the ordinary way. These doors are opened or closed simultaneously by the driver and getting into or out of the cab is thereby rendered easy. The cab is fitted with a band-brake acting on the hubs of both axles, a piece of apparatus which we think is most desirable. Curiously enough, however, the patentees inform us that the members of the London cab trade, with that hidebound conservatism which is losing our country so much trade, refuse to use the brake on the ground that they never heard of a brake for a two-wheeled vehicle. It is quite true that in the south of England, at any rate, the simple tyre brake acting on both wheels which is so common in foreign countries is never used, the only brake being the iron-shod drag-pole which sticks out behind and on to which the body of the cart is tilted. To our minds the Alington cab is a great improvement upon the ordinary hansom. Of course, if the doors are shut and the windows are open it is draughty, but even with the windows up the ventilation is good and the sensation is that of driving in a small brougham. From a personal trial of the cab we can congratulate the inventor on the comfort and comparative safety of his vehicle The cabs can be seen at, or hired from, Mr. J. E Gentle, Old Manor Yard, adjoining Earl's Court Station, but as yet there are only a few plying for hire.

We have also received from Mr. W. F. Stevenson of Boscombe a sketch and description of two improvements applied by him to the ordinary hansom. One is the substitution of a revolving glass hood in place of the guillotine window and the other is the substitution of a wheel on the "gravel iron" in place of the usual loop of iron. Neither of these improvements is new and the latter was brought to our notice in 1900 by Captain Dickson and described in THE LANCET of Sept. 29th, 1900, p. 981. The former modification has been applied to hansoms for some years, but both modifications are among the first to suggest themselves to anybody who studies the matter and we do not for a moment suppose that Mr. Stevenson was aware that his ideas had been anticipated.

TEST-TYPES FOR THE POCKET.



THIS appliance has been designed for the purpose of meeting the difficulty which from time to time arises from not having a convenient and ready form of types for testing the vision in patients' houses. It consists of seven cards, united by strips of linen, measuring 6½ inches by 4 inches, upon one side of which are printed Snellen's Distance Types and on the other types for reading; in addition the topmost card is perforated in its centre with a revolving pin which secures four strips of stout cardboard. At each extremity is a set of horizontal and vertical lines. These lines vary in thickness from those visible at 18 metres to 12, 6, and 4·50 metres respectively, while behind the lines is printed on the card a graduated arc, indicating the axes which they can be made to assume. This arrangement provides for the testing of cases of astigmatism, and thus the appliance forms a handy, complete, and compact visual test, especially adapted for use in patients' homes. The whole folds into a small space occupying about 6½ inches by 4½ inches by ⅛th of an inch, and can be readily carried in the pocket. The publisher is Mr. F. Davidson, Optician, 140, Great Portland-street, London, W., who supplies it at a trifling cost

PERCY DUNN, F R.C S.Eng.,
Ophthalmic Surgeon to the West London Hospital; Lecturer on Ophthalmology at the West London
Wimpole-street, W. Post-Graduate College.

CROWNHILL CONVALESCENT HOME.—The annual meeting of the subscribers to the Crownhill Convalescent Home, near Plymouth, was held on May 1st. The report stated that during the past year 259 patients had been admitted. The financial statement showed that the expenditure had amounted to £520 and that an adverse balance of £29 remained against the institution. Dr. C. A. Hingston, the founder of the home, was reappointed honorary physician.

THE LANCET.

LONDON: SATURDAY, MAY 9, 1903.

"Opticians" and Spectacle Prescribing.

A CONSIDERABLE amount of feeling has been excited in the minds of many members of the medical profession by the modern claim of spectacle-sellers to possess a degree and kind of scientific knowledge which would render them trustworthy advisers on all matters relating to the employment of the useful instruments in which they deal, and by the modern claim of the commercial bodies with which they are connected, or from which they obtain some kind of licence or diploma, to test the possession of this knowledge by means of examination. It is impossible to traverse the streets without seeing an announcement that So-and-so is an "ophthalmic optician," whatever this grotesque combination of words may be supposed to mean, and that he is not only prepared "to test the sight" of his customers but also to advise them with regard to the appliances by which any defects that he may discover can be rectified. An "optician," according to Dr. JOHNSON'S definition, is "one skilled in the science of the nature and laws of vision," and "ophthalmic," which does not appear in JOHNSON, is defined by the later authority of WEBSTER to be "that which has relation to the eye," so that the addition of the adjective to the description of a tradesman is at best a pleonasm, and frequently, without doubt, is a misleading one. Those who are thus described, however, have during the last few years not only held themselves out as competent or even exceptionally skilful advisers of the public with respect to their sight, but they have even gone to the length of recommending medicaments as well as spectacles and of selling lotions which have not always proved to be harmless. Quite recently an action was brought by one of these so-called "opticians" against a druggist who had supplied him with ready-prepared "eye lotions" for all cases, one of which lotions was productive of serious injury to the purchaser.

It must be admitted, of course, that spectacles were made and sold by the trade and were freely used by the public, as well as that a Worshipful Company of Spectacle Makers existed, long before the investigation of the eye as an optical instrument had been undertaken by physiologists; and it is not unworthy of note that the opinions held by the "opticians" of the pre-physiological days with regard to the refraction of the eye and its derangements were wholly and in every respect erroneous. In any book on "optics" written 50 years ago it will be found stated that short-sight is produced by undue convexity of the cornea, with consequent excess of refractive power, and that presbyopia is produced by gradual flattening of the cornea, with consequent gradual diminution of refractive power. Spectacles for short sight were only considered in relation to their [illegible] better distant vision; and, [illegible] ultimate loss of sight in chronic glaucoma were usually attended by a demand on the part of the sufferer for stronger and stronger reading spectacles, it became the custom of the "trade" to attribute the loss of sight to the strength of the glasses and solemnly to utter foolish warnings against the employment of any which were "too strong." Before the days of BREWSTER there was at least no common knowledge of the existence of the function of accommodation or of the possible nature of its derangements and long after his days the old errors were copied from text-book to text-book. In a thousand years physical opticians had done absolutely nothing to attain to any real knowledge of the functions of the eye as a seeing organ or of the various ways in which [illegible] functions were liable to be disturbed and but for [illegible] physicians they would to-day be very much where they were in China in the days of CONFUCIUS or in Egypt in those of the Shepherd Kings.

With the entrance of physicians and physiologists upon the scene all this was changed. The science of physiological optics was created by THOMAS YOUNG, the discoverer, among many other things, of astigmatism; and the slowly growing knowledge of the next quarter of a century was fully set forth and systematised in 1864 in the monumental work of DONDERS, himself the discoverer, again among many other things, both of hypermetropia and of the dependence of myopia upon elongation of the eyeball instead of upon faulty curvature of the cornea—a discovery which at once led to new views of the seriousness of the affection and of the principles upon which its treatment should be conducted. The power of accommodation, first recognised by KEPLER, had been analysed by YOUNG; and to its gradual diminution, instead of to an imaginary "flattening of the cornea," the phenomena of presbyopia at length came to be attributed, with the result that the visual errors thence arising were for the first time corrected on scientific principles. At a still later period the actions or defects of the ocular muscles became the subjects of medical investigation, largely in the United States of America; while the use of prismatic spectacles, first suggested by GIRAUD-TEULON, was placed upon a scientific foundation by SCHEFFLER of Brunswick. Even more recently, these have to some extent been superseded by surgical operations upon the muscles, either by tenotomy of any which are acting in excess or by advancement of the insertions of their antagonists, measures in respect of which, again, we have to admit a large indebtedness to America. In all this progress, by which the use of spectacles has been raised from a matter of often ignorant routine to the level of a science, every step has been made by medical practitioners, and not a single one by any "optician," either real or so-called; while not the least of its consequences has been to show that the treatment of optical defects of the eyes is in many cases a matter of very grave responsibility, which can only be safely undertaken under the guidance of complete medical and physiological knowledge.

We presume it will be universally admitted that even for the prudent discharge of the proper duties of their trade—that is to say, for the manufacture and sale of spectacles

—it is, on the whole, desirable that modern so-called "opticians" should have some knowledge of underlying principles and that they should be rescued from talking sheer nonsense as the ordinary daily jargon of the counter. It is, moreover, certain that the practically almost universal need for reading spectacles at 45 or 50 years of age can, in the great majority of cases, be safely and well supplied by rule of thumb, without further examination of the eyes than can be accomplished by any of the ordinary forms of optometer, while it may also be conceded that the majority of the public will be unwilling to pay a medical fee for advice on what they ignorantly conceive to be a very "*simple*" question indeed. The chief value of such advice, of course, is as an insurance against the existence of any actual or incipient disease of the eyes which a spectacle-seller would be liable to overlook and which might require something more than the ordinary convex glasses of a dioptre or a dioptre and a half. The conditions are precisely analogous to those which exist in relation to the sale of medicines by druggists. The man who is at once poor and rash, or perhaps who is rash without being poor, submits himself to what is known as "counter practice" and has something "put up" which it is supposed will meet the requirements of his case. The man who is not rash consults a physician and goes to the druggist with a *prescription*. Unfortunately, however, the spectacle-sellers of the present day have fancied that they have caught the physicians bathing and have tried to run away with their clothes. They have endeavoured to set themselves up as superior authorities and they call upon their trade organisations to assist them in this endeavour. They allege, perhaps not without some show of reason, that a certain proportion of medical practitioners have not studied the questions at issue and are less qualified to give advice concerning them than they are themselves. To whatever extent this may be true, the medical practitioners so situated would at least be conscious of their own want of information on the particular subject, would be fully alive to the possibilities of doing harm, and —not the least important element in the case—would have no spectacles to sell as a sole basis for remuneration. They would refer their patients to someone better fitted to bear the burden of advising them. In the meanwhile, commercial bodies of presumed respectability, such as the Spectacle Makers' Company, cannot be too careful not to assist their Freemen or others connected with them in assuming responsibilities which they are unfitted to discharge; and medical practitioners will act wisely in assisting the public to understand that many spectacle-sellers are not only ready, but even eager, to rush in where the practitioners themselves may properly fear to tread.

Aspects of Life Assurance.

THE *Journal of the Society of Arts* recently published an interesting paper read before the society by Mr. WILLIAM SCHOOLING, entitled "New Aspects of Life Assurance." The novelty mainly lies in Mr. SCHOOLING's treatment of his subject, in the attention which he calls to the evolution of the principles and practices adopted by life assurance societies, and in the ingenious comparisons with which he has been able to illustrate this branch of his topic. Incidentally, however, to the consideration of the historical and scientific aspects of life assurance in a lecture which will repay perusal in full, Mr. SCHOOLING makes some observations of a practical character which should be noted by those who contemplate insuring their lives and by medical men whose interests in such a matter are often very close.

The varied possibilities and combinations of life assurance deserve the close attention of all professional men and of none more so than medical practitioners who have little opportunity for making advantageous investments and little time to study the safest methods for disposing of savings which in many cases are not large. The duty of providing for the contingencies of old age and death need not be dwelt upon, but it must be borne in mind that some will desire one form of assurance and some another, one man, for example, wishing for a life income after a certain date, another for a life income with the repayment of a capital sum to his personal representatives, and another being content that his wife and family should receive the proceeds of his assurance, without desiring to derive any income from it during his life. With regard to such as these Mr. SCHOOLING calls attention to the fact that different companies devote themselves more than others to different forms of assurance in which they, so to speak, specialise, and observes that companies which confine their business to life assurance generally give better results to their policy-holders than offices which transact many different branches of assurance business. Some companies, again, he remarks, by way of example, give relatively superior results under endowment assurances and relatively inferior results under whole life policies, and others are exceptionally good for policy-holders entering at the older ages. While deprecating such differences he urges the advisability of comparing the results obtainable from different offices in accordance with the nature of the assurance desired, and suggests that there is an opening for the development of the specialist in life assurance who should be familiar with the best points of all the companies and ready to advise intending policy-holders as to their relative merits. For the methods adopted by the best British Life Assurance Offices Mr. SCHOOLING has nothing but praise and he calls attention to the favourable conditions in which they conduct their business under the Acts which regulate their procedure.

In the latter part of his paper dealing with the varieties of form which life assurance is capable of in the hands of modern experts, Mr. SCHOOLING illustrates his topic by reference to those who may desire a fixed and safe interest upon a capital sum during their lives and the certainty of an unimpaired capital for their survivors, but who at the same time may wish to have a substantial sum of money to devote immediately to some special object As an example of such a special object Mr. SCHOOLING takes a possible donation to a hospital and points out that a donation of £1000 to such an institution may be of more advantage to it at a time of need than an annual subscription of £60 during the subscriber's lifetime, while the donor may prefer the position with relation to the government of the hospital which such a gift, if made during his lifetime, would secure to him. The tables by which he explains this show, if we select examples from them, that a man 40 years of age who desires to invest £10,230 so as to receive a safe 3 per cent. interest upon that amount, with the return of his capital unimpaired at his death, and to give an immediate present of £1000 to a hospital or to devote such a sum to any other desired object, may deduct £1000 from the £10,230, spend £4168 as a single premium to secure £10,230 at death, and with £5062 buy a life annuity of £307 which will give him interest at the rate of 3 per cent. on his original £10,230. Or, again, a man 40 years of age, instead of paying a yearly subscription to a hospital of £50, which may be taken as representing the interest upon £1688, can pay to the institution £1000 and to a life office £688, thus securing from the latter £1688 on his death. The variations which may be introduced into operations of this kind owing to the various forms of policy initiated by different life assurance companies are numerous, and Mr. SCHOOLING would call the attention of hospital committees to the advantages which they are capable of affording.

In considering these and other financial operations connected with life assurance and in comparing them with other possible plans which seem capable of bringing about like results, the most important point to be borne in mind is the very high degree of safety afforded by the sound pecuniary position of the great life assurance companies. Many methods of investment may seem to promise a more rapid increase of capital than they do, but none can be held to do so combined with the same security, a security which, be it remembered, is not affected by the premature death of the investor, but which, on the contrary, safeguards his survivors against the disastrous consequences of an event which none can foretell or avert.

Remedial Measures against Plague in Hong-Kong.

THE report recently issued by Dr. W J R. SIMPSON on the Causes and Continuance of Plague in Hong-Kong contains a large mass of interesting information. It should also be an extremely helpful document to the Government for Dr. SIMPSON advises remedial measures with no uncertain voice and out of a great practical experience. The prevention of plague in Hong-Kong presents extreme difficulties inasmuch as the causes of the disease lie both within and without the colony, so that prophylactic measures to be effective must deal with both sets of factors. The whole of Southern China is more or less smitten with plague and the proximity of Hong-Kong to such an extensively infected area entails upon the colony considerable and permanent risk. The danger is increased by the fact that the population of Hong-Kong is largely derived from Kwangtung, upon which province Hong-Kong is mainly dependent for its food-supply. The population is constantly changing and numerous persons are frequently being brought to the colony from infected districts. No amount of precaution which is within the bounds of practicability can do more, therefore, than lessen the risk to the British colony so long as the empire of China takes no action to expel the disease.

But apart from the ever recurring infection from the Chinese coast, Dr. SIMPSON shows that plague is endemic in Hong-Kong itself. This endemicity is dependent upon several obvious causes. Firstly, it arises from infection among rats and pollution of the soil in rat holes. It has been found in Hong-Kong that there is nearly always an infection of the locality by plague-stricken rats before cases of plague occur among human beings. The insanitary condition of the interior of the houses is a second and most important cause. In the Chinese quarters of Hong-Kong the rooms are long and narrow and the lower floors are remarkable for their darkness; they are also frequently damp and densely overcrowded. The admission of sunlight into the dwelling-rooms is obstructed by the subdivision of the rooms into several compartments in accordance with the almost invariable Chinese custom. Each cabin is let to a separate tenant and not infrequently accommodates a whole family. A perpetual spread of plague is also brought about through the clothes of people who have died from plague. These are frequently surreptitiously removed before disinfection and taken to a healthy dwelling-place to constitute a new focus of disease. Lastly, the bodies of persons who have died from plague are commonly placed in the street and left there to be removed by the sanitary authorities. In this way not only does the body form a possible factor in spreading plague but another danger is added for the public—namely, the concealment of the infected houses. In order to guard against the importation into Hong-Kong of persons suffering from the disease and at the same time to combat the conditions naturally existing in the colony, Dr. SIMPSON has recommended to the Government the following measures: (1) notification of plague from China by weekly bulletins from consuls; (2) the inclusion of a special plague organisation in the sanitary administration; (3) a reorganisation of the sanitary department to include medical inspection of shipping and junks and the appointment of a Sanitary Commissioner for the Colony; and (4) the amendment and consolidation of the public health ordinances. He believes that with a trained and special organisation it will be possible to keep the disease in check and under control so as to prevent it reaching those dimensions which alarm the population, prove disastrous to the colony, and render Hong-Kong a source of anxiety to those who have trade relations with it. The preventive measures required are extensive and must involve an immense amount of labour. Amongst the first procedures to be adopted is a campaign against rats. The preparation and distribution of rat poison or of the Danysz bacillus must be arranged; the bacteriological examination of rats must be undertaken to discover which are infected so that the house or street from which the infected animals are brought may be detected; old, dilapidated, and rat-ridden houses must be rendered rat-proof; and ships must be inspected to insure that they possess the proper appliances to prevent rats passing from the ships to the shore or from the shore to the ships. Then as far as possible all concealed cases of plague must be traced and the patients removed to hospital; provision must be made of temporary accommodation for the healthy inmates of a plague-infected house; the cleansing and disinfection of such a house and all infected clothing must be undertaken; and, finally, emigrants must be inspected and their personal effects disinfected before leaving port.

Dr. SIMPSON states that the Government has already taken steps to organise a small but permanent staff trained in the work for carrying out the above duties. But he urges upon incontestable grounds that the sanitary administration of the colony requires to be placed on a wider basis in order that the complicated and serious health problems which always arise in a thriving and expanding commercial centre should be economically and successfully dealt with. He also remarks on the airy absence of responsibility that has hitherto prevailed and which, we may be sure, has counted for a good deal in the persistence of disease in Hong-Kong. "The most noticeable feature in regard to the sanitary matters of Hong-Kong is that no one is responsible," says Dr. SIMPSON, and he proceeds to make suggestions for altering this happy-go-lucky state of affairs. He recommends that all municipal health matters should be brought under one department, controlled by a sanitary or health commissioner who would be the administrative officer. We have said enough to show that there is more than ample work to occupy the whole time of such an officer and we hope that the appointment will be made at an early date. In addition to being president of the sanitary board the health commissioner would administer the several branches of the public health department dealing with the questions of water-supply, sewerage, and drainage, while he could also advise the Government upon the questions constantly arising in a community crowded with natives whose ideas of hygiene are extremely rudimentary. He would be responsible to the Government for the efficient working of the department and, like the director of public works, should have a seat on the Legislative Council. The general health of the community in a colony like Hong-Kong is of national importance and we trust that the Government will fully consider Dr. SIMPSON'S proposals and recommendations and speedily put into force the administrative reforms which he has advanced.

Cremation and Crime.

IT is not here our purpose to deal with the sentimental or other objections to the destruction of human remains by incineration; we merely wish to direct attention to facts which afford material for valid argument against the process recently provided for by Act of Parliament. In the first place it has been alleged that cases of simulation of death might occur and that persons in a state of suspended animation might have their lives extinguished by the means intended only for the destruction of their bodies. We have dealt with this question on former occasions and have pointed out that in the vast majority of instances there is no real foundation for the stories of premature burial or intended burial. No doubt in certain conditions—e.g., in the case of newly-born children—death may be only apparent and long-continued efforts at resuscitation will succeed in restoring such children to animation. But the chances of a living body thought to be dead being reduced to ashes are too infinitely remote, in our opinion, to merit serious consideration. Moreover, a living body is no more likely to be cremated than to be disposed of by the usual form of sepulture.

A far more serious objection to cremation is the possibility that a person may have been poisoned and that by burning the body the proof of the crime will be made to vanish for ever. During the trial of CHAPMAN, or KLOSOWSKI to give him his right name, at the Central Criminal Court the presiding judge took occasion to animadvert upon the Act recently passed by the Legislature. His lordship must either have been ignorant of the stringency of the regulations drawn up by the departmental committee appointed by the Secretary of State for the Home Department, or the grim facts of the cause just determined under his direction had unconsciously biased his judicial mind. Would it not be nearer the truth to say that had KLOSOWSKI applied for an order for cremation of the body of his first known victim the lives of the other women would probably not have been taken? His application would have led to his arrest. In the case of indestructible poisons the murderer who has knowledge of their properties may live in dread of the discovery of his crime, but would he not be in greater risk of that discovery were he to court inquiry of a most searching character by applying for an order for cremation? We do not believe with some that KLOSOWSKI'S long immunity from detection will in consequence of the recent law lead to an epidemic of murder by poisoning. On the contrary, we feel that his conviction at a time when impunity must have seemed probable will do much to check such crimes. Another reason which is advanced by the opponents of cremation is that an innocent person suspected of having administered poison with fatal results would by the destruction of the body be unable to disprove his guilt. One of the greatest of living authorities on medical jurisprudence—Dr. BROUARDEL—gives the weight of his opinion in support of this contention when he says: "There is here a real social danger and I should reproach myself if I did not lay stress upon it, especially with regard to the suspicions which may weigh indefinitely on an innocent person, incapable henceforth of proving his innocence" The possibility of such a catastrophe must be admitted and is the gravest indictment that can be drawn against cremation as a legally constituted procedure. Therefore to justify the measure it must be shown that unfounded suspicions of criminal poisoning are rare to a degree Care also must be taken that the regulations relating to cremation are so strict that only by the barest chance could there be a miscarriage of justice, although in the event of such miscarriage the partial evil is more than outweighed by the universal good, the individual mischance being eclipsed by the gain of the community.

As a means of combating disease, both by prevention and by effacement, cremation has certainly greater claims than earth burial. A virulent epidemic may be checked in its course and insanitation, due to the near proximity of graveyards to centres of dwelling and to the frequent renewals of burial in the same ground, would in great measure be removed. Taking an impartial survey of all the factors of an intensely interesting and difficult problem we feel compelled, though with some diffidence, to subscribe to the terms of the law which Parliament has seen fit to enact. We say this with all reverence for the sentiments of those who from long years of tradition have founded their faith, perhaps too literally, on the hallowed words, "earth to earth," and with full knowledge that the arguments against cremation are not all sentimental.

Annotations.

"Ne quid nimis."

THE BRITISH OPHTHALMIC HOSPITAL, JERUSALEM.

THE annual report of the Grand Priory of the Order of the Hospital of St. John of Jerusalem in England, just sanctioned for issue by the Chapter of the Order, contains, in addition to the usual detailed and important history of the ambulance work of the Order in England, in India, and in the colonies, the fifteenth annual report of the British Ophthalmic Hospital at Jerusalem, a charity which is maintained by the Order and is entirely under its control but for which contributions are sought from beyond its ranks. The hospital has lately been enlarged, at the cost of a single anonymous donor who stipulated that there should for the future be two resident surgeons instead of only one as heretofore, and it is now able to make up 50 beds, so that its power of providing for the enormous prevalence of eye disease, not only in Jerusalem itself but in all the surrounding country, is about to be greatly extended. The senior surgeon, Dr. W. E. Cant, has held his office with great distinction for about 12 years, during the last four or five of which he has had assistance during the busiest period of the year only, and he is now to be reinforced by Dr. T. Harrison Butler, an Oxford graduate and formerly Radcliffe Travelling Fellow, who assisted him during last summer and is about to accept a three years' engagement from the Order. The enlargement of the hospital and the increased number of beds and of in-patients will also render it necessary to engage more nursing aid from England, and the cost of maintenance is likely to be so seriously increased that the London committee is very desirous to enlist the sympathy and assistance of benevolent persons in this country who may be willing to assist in the good work which is being carried on. In truth, the magnitude and value of that work can hardly be overstated. It is a fundamental principle of the Order that no attempt at religious proselytism is permitted in the hospital and the result of this wholesome rule is that members of all the creeds in Palestine are to be found living within the wards in perfect harmony and practically learning the useful lesson of tolerance and of mutual help. Within these wards the most fanatical Mussulman learns to regard the Christian or the Jew only as a fellow sufferer and learns also that the Christian is actuated by no other than benevolent feelings towards his fellow creatures who differ from him in matters of belief. Universal testimony is borne alike by the Pasha of Jerusalem, by the Chief Rabbi, and by the Christian Bishop as to the absolute freedom and complete protection in respect of religion afforded to all creeds alike and as to the beneficial effect of this freedom and protection in bringing about the gradual growth of charity and of goodwill. The surgical report for the year ending Sept. 30th, 1902, gives the number of in-patients admitted as 674, the new out-patients as 6062, the total attendances on out-patients as 19,196, the operations as 1271, and those requiring anæsthetics as 680. A very large proportion of the operations are for changes in the form of the eyelids produced by trachoma and in dealing with these Dr. Cant is said to have attained an extraordinary degree of dexterity and of success. There were 62 extractions of hard cataract during the year and in addition to the familiar "Egyptian" ophthalmia, which is always abundant and in which the hospital is continually rescuing sufferers from loss of sight, the out-patient department presented nearly every form of affection which is met with in this country or in Europe. The result of its work is that the doors of the hospital are not only besieged, often before daylight, by great numbers of the poorer residents in Jerusalem itself, but also by the fellaheen from all parts of the Holy Land, many of whom make long journeys for the sake of a single consultation. It would be impossible for English charity or English skill to have a better representative in the East than the hospital affords and its work, material as well as moral, is deserving of every possible assistance. The headquarters of the London committee are at St. John's Gate, Clerkenwell, at the Chancery of the Order, where information about the hospital will be promptly given and donations in aid of it will be gladly received.

THE RELATION OF LEPROSY TO THE USE OF FISH AS FOOD.

IT is generally known that Mr. Jonathan Hutchinson has recently made a tour in India for the purpose of obtaining information bearing upon the hypothesis which assigns a foremost position to the use of unwholesome fish as food in the etiology of leprosy. A short account of the results of his inquiries has appeared in the *Times*, but we presume that this is merely a preliminary notice and that fuller information will be forthcoming. Mr. Hutchinson's general conclusion is that as regards leprosy in India there are no facts which controvert or render untenable the fish hypothesis and that there are some which afford to it a support which he considers to be unassailable. The commission which, 12 years ago, was sent to India to investigate the whole subject of leprosy gave careful attention to this point and, while fully admitting the plausibility of the fish hypothesis, finally rejected it on the ground that a considerable number of lepers in the asylums of India alleged that they had never eaten fish. Dissenting from this conclusion and believing that the statements of alleged facts to which the commission had trusted were in some respects erroneous, Mr. Hutchinson wished to go over the ground again and to examine these contentions more critically. He visited many of the leper asylums and elicited much interesting information. He likewise maintains that he has exposed many fallacies which would easily mislead the members of a commission unless care was taken personally to verify the documentary evidence. For instance, in one asylum in the Punjab a tabulated schedule had been prepared for Mr. Hutchinson by the native medical superintendent, according to which nearly 40 men alleged that they had never eaten fish. Mr. Hutchinson questioned them one by one with the result that only one man persisted in the denial. In the account before us many examples are given which, Mr. Hutchinson considers, afford strong support to the fish-eating theory To give an example. The Ceylon waters are much less productive of fish than those of the Indian coast and of certain groups of islands. In Ceylon the incidence of leprosy is less than two per 10,000. On the little island Minicoy, closely adjacent, which exports fish and where the inhabitants are said to have four fish meals a day, the proportion is possibly little short of 150 in 10,000. Mr. Hutchinson as the result of inquiries made last year in South Africa is convinced, however, that it is an error to attempt to apply the fish hypothesis exclusively, since in a certain small number of cases it seems certain that the disease may be conveyed by eating food directly from the hands of a leper or by receiving in any other way the pathogenic bacillus by the mouth; hence he concludes from his observations that whilst fish-eating is the invariable originating cause of leprosy it is not the sole cause of its prevalence. Having once originated in a community it may possibly spread to some slight extent by what Mr. Hutchinson calls "commensal communication." It will be observed that the above remarks apply mainly to leprosy as existing in India. A meeting will be held at the Polyclinic on Friday next, May 15th, at 2.30 P.M., Lord George F. Hamilton, Secretary of State for India, taking the chair, when Mr. Hutchinson will report the results of his tour. Discussion will be invited and an interesting debate is to be expected.

THE POTENTIALITIES UNDER THE PAVEMENT.

EVIDENCE has been forthcoming on more than one occasion that the roadways and pavements of London need to be disturbed with some care, for there are forces locked up there which bad management might easily release with disastrous results. It is enough to make the nervous pedestrian shudder when he realises that within a few inches below him are electric cables of 10,000 voltage in close proximity to high-pressure gas mains. Near these, again, is the water main the escape of water from which is calculated to rot the insulator of the cable or the joints of the gas conduit. Some alarm was created in the Strand last Sunday in the neighbourhood of the building operations being carried on near the Savoy Hotel by the occurrence of a subsidence of a considerable area of ground which involved the pavement, and a four-inch gas main and three electric cables were exposed to view and submitted to a dangerous degree of twisting. The subsidence proceeded for some hours and the danger of the situation was increased by the fact that being Sunday there were no workmen at hand to give assistance. Eventually it was discovered that the collapse was due to a load of bricks which weighed about eight or nine tons pressing upon the roof of some obsolete cellars and it is reported that the whole neighbourhood is honeycombed with cellars of an ancient date. The bricks were removed as quickly as possible and thus all danger was averted but not before a considerable escape of gas had taken place. It seems incredible that such big building operations should have been conducted before the honeycombed condition of the foundations was ascertained. It appears to us that the contractors must have exhibited great carelessness or misjudgment in not having taken steps to provide that the ground destined for building operations was firm enough to stand the weight of a load or so of bricks. In these days of all sorts of potentialities beneath the pavements the greatest care needs to be exercised in order that the paths of gas, water, and electricity may not be interrupted, for in the absence of such care disaster may readily ensue.

THE PREVALENCE OF SMALL-POX.

THE Local Government Board for Scotland intimates that during the period from April 16th to 30th inclusive 1 case of small-pox has been notified to it—viz., from the parish of Peebles. Small-pox continues to spread chiefly in the Midlands and in the North of England. With regard to Liverpool Mr. Weir, M.P., has given notice that he will ask the President of the Local Government Board whether he is aware that during the last six months there have been some 1400 cases of small-pox and 90 deaths and whether he will consider the desirability of appointing one of the Board's medical inspectors to inquire into the measures which are being adopted by the health authorities to cope with the disease. At Leicester on April 30th there were 90 cases of small-pox under treatment, while cases are still being reported from Nottingham, Coventry, Manchester, and Cardiff, and at midnight on May 3rd there were 48 cases under treatment in the hospitals of the Metropolitan Asylums Board. In Dublin the total number of cases notified last week was 25. Difficulties arise from concealment of cases and last week nine cases so concealed were discovered. We notice that Mr. J. Byrne Power, medical officer of health of Kingstown, states in his April report: "What has been accomplished in Kingstown as regards both primary vaccination and revaccination has been mainly owing to the coöperation of the Catholic clergy." We commend the example of their Roman Catholic brethren to the clergy generally.

"PSEUDO-VARIOLA."

WE have recently received a small brochure which is dated August, 1901, and is not without interest in its bearing on the question at issue between Barbados and Trinidad to which we referred in a leading article in THE LANCET of May 2nd, p. 1248. For it deals with the "eruptive skin disease" which the authors say "has been prevailing extensively in many parts of the United States for the past three years," and therefore was doubtless the same varioloid epidemic which afterwards prevailed in Canada and later in the West Indies. The authors are Dr. Simonton, Dr. Sloan, and Dr. Porter, who give their experience of this "highly infectious" disorder as it appeared in the far west in 1900-01 in the mining town of Roslyn, Washington, situated about 2500 feet above the sea level. Here in a small community of 4000, not one in ten of whom had ever been vaccinated, this disease spread to such an extent that 1500 cases were observed. Not one of these cases was fatal and the writers confess that if it had been true small-pox such a result in an unvaccinated community would be without a parallel. They argue that, similar as it was to variola vera in some of its features, it differed in others and ask why it should not be regarded as a distinct affection, as distinct as rötheln is from measles, or pseudo-diphtheria from diphtheria. A large number of the cases, especially in children, were of a very *mild type—there being no premonitory symptoms*, while there was a scanty papular rash which became vesicular but never pustular. In the more severe cases there was premonitory fever preceding the eruption of the papules on the face and the trunk which, like varicella, appeared in "crops," and the vesicular stage assumed a semi-confluent or confluent character. But no pustulation or pitting occurred except in cases where the vesicles had been irritated by scratching. Nor did any complications or sequelæ arise. The affection which they thus describe is certainly very similar to many of the cases observed lately in Trinidad, but not to those which, according to Mr. J. F. E. Bridger, more nearly resembled true variola. The experience of Roslyn, too, was like that of Trinidad in that quarantine could not be carried out and infection was freely disseminated. Dr. Simonton, Dr Sloan, and Dr. Porter further aver that not only did the unvaccinated children exhibit the disease in its mildest form, but that in the few cases in which they persuaded the people to be vaccinated this measure had no appreciable effect in preventing the disease and vaccination was successfully performed in those who had recently convalesced They add, somewhat significantly it seems to us, that Roslyn, unlike some other towns of the United States, perhaps owed its freedom from fatalities to the fact that no cases of true small-pox were mingled with those of this "pseudo-variola"—thus emphasising the distinction upon which much stress has been laid in Trinidad that if such a disease were small-pox it *must* be more fatal than has been the case in these outbreaks. Since there is apparently no very marked criterion other than this of mildness of type to distinguish the "true" from the "false" disease, it would seem to be incumbent on sanitary authorities to be as vigilant in their preventive measures in the one case as in the other—until, at any rate, it be more plainly established that a new disorder is to be added to the nosology.

CLAY-MODELLING IN THE STUDY OF OSTEOLOGY.

In the March-April number of the *Bulletin of the Johns Hopkins Hospital* Dr. Robert O Moody of the University of California describes the method of clay-modelling which all the students in the osteology class of that university have to learn in addition to making drawings of the bones of the skeleton The necessary apparatus consists of a board and two modelling tools The board should be a piece of smooth kiln-dried wood, about 24 inches long, 20 inches wide, and three-quarters of an inch thick. It is well to have it coated with boiling paraffin to prevent the clay from sticking or the board from warping. The best potter's clay is used after having been passed through a sieve and homogeneously mixed with water. The model of each bone should be completed while the clay is still in a plastic condition ; it is not desirable to let the clay harden and afterwards to carve and to finish the model. The amount of time given to this work is about 24 hours a week for seven weeks. During the first week the clavicle, scapula, and sternum are modelled, and during the second week the humerus, radius, ulna, and ribs.

THE TREATMENT OF INCIPIENT MENTAL DISEASE.

In his presidential address, delivered on March 2nd at the annual meeting of the New Zealand Branch of the British Medical Association (an account of which by our New Zealand correspondent will be found at p. 1341 of our present issue), Dr. S. A. Gibbs of Nelson gave an outline of what would undoubtedly constitute a great improvement in the treatment of cases of incipient mental disease. He said that facilities ought to be provided for those who might, and would, offer themselves for treatment in institutions if the stigma at present attaching to the idea of a lunatic asylum could be avoided. Voluntary admission of mental sufferers into places suitable for their reception was possible in some countries, but no such system existed in New Zealand except for one special class of the mentally afflicted—namely, the dipsomaniacs. The principle was thus admitted to a certain extent and he thought that the benefits obtainable in this way might be made accessible to a larger class of cases by centralisation of the control of the general hospitals and asylums under the Department of Public Health. Incidentally he gave credit to the Government for having established this department, which was doing valuable work as was also the pathological laboratory under Mr. Gilruth. Central control would allow the scope of the general hospitals to be widened and would allow nurses to obtain special training at the asylums in mental diseases, and by transfers each general hospital could be provided in time with nurses who had received this special training. The amalgamation suggested might also be followed by the establishment of a New Zealand staff of hospital nurses, which would be a step in advance, and the central authority could then arrange for the transfers necessary to secure the special training. Dr. Gibbs gave instances where incipient insanity had been successfully dealt with by timely care and emphasised the point that under present conditions there was a natural disinclination on the part of the patient and his friends to incur the stigma which committal to an asylum involved. Dr. W. E Collins, in moving a vote of thanks to the President for his address, said that for some years he had been of the opinion that there should be an intermediate establishment between the hospital and the asylum for the mentally diseased and he protested against the use of the terms "lunatic" and "asylum." It was monstrous that those who were diseased mentally should be classed as lunatic and a reform was needed ; the term "hospital for the mentally diseased" would lessen the stigma in many minds. He also considered that the practice of taking patients to the police cells for examination had a deterrent and prejudicial effect on patients and friends and was unnecessary. Dr. James Mason, chief health officer, who seconded the motion, said that medical practitioners themselves were a good deal to blame for sending to the asylums persons who should not be there—old persons who should be found in the "ingle nooks" of their families. By reason of the large number of such persons sent into asylums the very reforms asked for were rendered impossible and the fault of the non-provision of such establishments as were now suggested did not lie altogether with the Government.

POOR-LAW MEDICAL OFFICERS IN THE HIGHLANDS AND ISLANDS OF SCOTLAND.

The parish council of Barra recently advertised for a medical officer and public vaccinator. The salary offered was £119 and as a further inducement other appointments were allowed to be held and private practice was allowed to be taken. We have upon various previous occasions reminded our readers that no Poor-law medical post should be taken under the Scottish Poor-law unless assurances have been obtained from the parish council regarding fixity of tenure, adequate salary, a free official residence, and a free annual holiday—i.e., payment of a locum-tenent. With regard to the appointment under consideration, Barra is an island in the Hebrides and the parish includes several other islands which are sometimes difficult of access. It will also be remembered that a Scottish parish council has the right to dismiss its medical officer without giving any reason and in 1898 the parish medical officer of Barra was so dismissed, as may be seen in a return applied for by Mr. Weir, M.P., and ordered by the House of Commons to be printed on August 8th, 1902.

AUTOMATIC COUPLINGS ON RAILWAYS.

On Wednesday, April 29th, a lecture was delivered at the Society of Arts upon Automatic Couplings, in the course of which the lecturer stated that since the year 1872 some 30,000 railway servants had been injured or killed while they were coupling or uncoupling wagons on the railways of the United Kingdom. On the previous Wednesday, April 22nd, the question was raised during the discussion of the estimates for the Board of Trade. This department is a kind of Government whipping-boy, or, to quote Mr. Gibson Bowles, its good deeds and its bad deeds extend over almost every department of modern life. So far as we can see every industrial trouble which arises is laid at the door of the Board of Trade but we are bound to say that this department does not make as much use as it ought to of the powers intrusted to it. Mr. F. W. Evans, formerly secretary of the Amalgamated Society of Railway Servants, in a letter to us concerning automatic couplings, refers to Mr. Gerald Balfour's speech in the House of Commons on the matter. Mr. Balfour implied that no really satisfactory form of automatic coupling had yet been invented. Perhaps not, but we should have thought that out of the very numerous forms of automatic coupling which have been invented, and we believe there are some 1500, there must be one which would lessen the risks undergone by shunters. We are quite aware that railway directors have to look after their shareholders' interests and that many poor persons draw the whole of their income from investments in railways, but still we believe if the directors of any company were to appeal to their shareholders and to say—Will you agree to your dividends being slightly reduced in order that we may make a beginning in substituting automatic couplings for those in use?—that no shareholder would refuse. Mr. John Ellis, in the debate in the House of Commons, referred to Mr. Ritchie's Railway Employment Prevention of Accidents Act, 1900, and asked why the Board of Trade had not carried out the powers given to it under that Act. Mr. Gerald Balfour replied that the Board had done what it could. All we can say is that the Board had better try to do a little more We are quite aware that very often workmen will not use life-saving improvements—e.g., the case of the Sheffield grinders and fans, respirators, and the like—but all the same the companies should endeavour to lessen the present risks to life.

A SURVIVAL OF "SIGNATURISM."

THE practice of rice- or starch-eating referred to in THE LANCET of April 25th, p. 1186, is not peculiar to Tyneside, and indeed seems to be universal throughout England. It is certainly often met with in Hampshire villages, where it is no unusual thing for a young woman of the humbler classes who is bent, as the phrase goes, on "looking interesting," to make herself very ill with starch-eating, the eating of tea-leaves, vinegar-drinking, and so forth. Starch, blue or white, is supposed to act like arsenic, clearing rather than rendering pale the complexion; at least, this is the opinion of villagers. Doubtless this pernicious custom, which may account for much of the anæmia of domestic servants, can plead a respectable antiquity. It is certainly too old to have been learnt in the fashion columns of modern journals. It is probably older than those false ideals of female beauty which prevailed in the beginning of the last century and in the eighteenth century when tight-lacing, sloping shoulders, and various kinds of etiolation, abnormally small hands and feet, fainting fits, and an unhealthy pallor were thought to be elegant, and when dandies such as Lord Byron drank vinegar and starved in order to combat a tendency to obesity. Rice- or starch-eating is in all probability the original of all these practices and may be said to be derived from the "signaturism" of the Middle Ages, which prescribed a medicine made from a white substance as a means of producing pallor. In the seventeenth century Sir Kenelm Digby was famous among the fair sex for his "cosmetic or beautifying water," the chief ingredients in which were six drachms of white lilies, orris roots, white lead, fine sugar, white bread crumbs soaked in milk, borax, alum, camphor, the white of an egg, and other substances, doubtless also white in appearance. In France, during the same period, the Queen of Louis XIV. used a somewhat similar mixture, which, when well shaken up, resembled milk. Its chief ingredient was, however, water "that runs from under the wheel of a mill." Both these famous cosmetics were used externally only.

THE DISTRIBUTION OF PLAGUE.

As regards the Cape Colony the acting medical officer of health states that for the week ending April 4th the condition of the various places mentioned below as regards plague was as follows:—At the quarantine station, Saldanha Bay, 2 patients still remained under treatment in the hospital. The s.s. *Nerasa* was granted a clean certificate and was permitted to sail on March 30th. At Port Elizabeth 2 cases of plague were discovered—namely, 1 native male who was admitted to hospital on March 31st and died on the following day, and 1 native female who was found dead on April 3rd. At the plague hospital, Port Elizabeth, 8 patients were discharged recovered during the week, leaving 15 cases under treatment. Plague-infected rats continued to be found in the town during the week. At East London 2 further cases of plague were discovered, namely, 1 Indian male who was discovered on March 29th, dying on the same day, and 1 native male on the 30th. Two patients remained under treatment at the plague hospital. Plague-infected rats were found in the town during the week. 3 patients remained under treatment at the plague hospital, King William's Town, and plague-infected rats were discovered in the town during the week. At Graaff-Reinet no cases of plague and no plague-infected rats were discovered in the town during the week. As regards Hong-Kong, a telegram from the Governor received at the Colonial Office on April 28th states that for the week ending April 25th there were 79 cases of plague and 72 deaths. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on May 1st states that for the week ending April 30th there was 1 case of plague which proved fatal.

THE X RAYS IN LYMPHADENOMA.

RADIOTHERAPY is so new that probably only a small part of its utility is known. The remarkable results obtained in lupus and in some forms of malignant disease raise the hope that it may prove valuable in many other conditions. In lymphadenoma some diminution of the enlarged glands has been reported by Dr. Pusey[1] but, so far as we know, no such complete observations as the following ones published by Dr. N. Senn of Chicago in the *New York Medical Journal* of April 18th have been recorded. A man, aged 43 years, had extensive enlargement of the cervical, axillary, and inguinal glands and of the spleen. The disease began with cervical enlargement 12 months before. He was anæmic and the blood contained no abnormal cells. Arsenic and iron were prescribed and on March 7th, 1902, daily exposures to the x rays were begun, one minute each being allowed for the right side of the neck, the left side of the neck, the neck from before backward, the neck from behind forward, each axilla, each groin, and the spleen. A current of 60 volts and eight ampères was used with a tube at a distance of 12 inches from the surface. On April 7th the glands were diminished and the chest was red and pruriginous. The current was reduced to 42 volts and six ampères. Six days later the voltage was reduced to 28. Blisters formed on the chest and the neck, naturally dark, turned dark brown. From April 16th to 23rd the exposures had to be confined to the neck, back, and groins, as the chest was the seat of extensive burns. On the 24th all the glands exposed to the rays had nearly disappeared and the hair on the part of the head exposed and in the axillæ and on the pubes had fallen off. The neck was blistered and the nipples were discharging pus. The treatment was suspended. Two weeks later the patient was much improved and was able to return to business. No enlarged glands could be discovered. When seen again on August 1st he felt well but had recently noticed slight enlargement of the cervical and axillary glands. The enlarged glands were treated by exposures of two minutes (for each group), with a current of 28 volts and six ampères, and the swellings promptly disappeared. No relapse has since occurred and the patient is in perfect health. In a second case a man, aged 53 years, was seen in the spring of 1902. Ten years before he noticed slight enlargement of the cervical glands and then the tonsils became swollen and painful. A little later the glands in the back of the neck, the axillæ, and the groins were affected. Arsenic, iodides, and cod-liver oil appeared to be useless. To regain health he lived an out door life in the mountains. After a year the glands were softer but not smaller. The appetite improved and weight was gained. The glands further enlarged until some of the cervical ones reached the size of a hen's egg. On examination the neck was bulging from glandular enlargement and a chain of glands extended from the axillæ to the epitrochlear regions. Some of the trochlear glands had reached the size of a chestnut. The inguinal glands were greatly enlarged. A gland of the size of a hen's egg was felt in the abdomen to the right of the umbilicus. The liver was palpable below the costal arch. The spleen was enlarged but not palpable. The tonsils were enlarged. Examination of the blood showed hæmoglobin 73 per cent. and erythrocytes 3,875,000 and leucocytes 208,000 per cubic millimetre. The leucocytes consisted of small mononuclear lymphocytes 78 per cent., large mononuclears 14 per cent., transitional forms 2 per cent, and polynuclears per cent. The x rays were applied to the affected glands on each side every alternate day, from five to seven minutes being given to each part. After four or five sittings the patient noticed softening and diminution of the glands. After 15 sittings there were slight dermatitis and symptoms of toxæmia. The patient lost appetite and the anæmia increased. The treatment was suspended. Three weeks later his health was much improved and he had gained 11 pounds in weight. The glands were much diminished and the skin which had been exposed to the rays was pigmented. Examination of the blood showed hæmoglobin 85 per cent. and erythrocytes 4,450,000, and leucocytes 76,000 per cubic millimetre. Exposures of seven minutes were given. After 12 sittings there were slight dermatitis, pigmentation, and loss of hair, and toxic symptoms more pronounced than after the first series of applications. Only one small gland could be felt above the right clavicle and one behind the sterno-mastoid muscle. The axillæ were normal and the inguinal glands had almost disappeared. The leucocytes were 46,500 per cubic millimetre. The spleen extended to within a finger's breadth of the iliac crest. The constitutional disturbance which accompanied the diminution of the glands is ascribed by Dr. Senn to absorption of the products of their degeneration. The patient has written recently that he is in perfect health and that there are no signs of relapse. The remarkable success of the x-ray therapy in these cases certainly indicates its trial in a disease but little amenable to treatment.

---

[1] Journal of the American Medical Association, April 12th, 1902, p. 911.

ELECTRICITY AND THE FOOD PROBLEM.

ELECTRICITY would appear to have something in common with the forces of plant life and it is just possible that some day the world's food-supply will be furnished by its means. Already we know that when intense electrical discharges occur in air nitric acid is produced which, when neutralised with soda, potash, or lime, furnishes the indispensable nitrate for plant life. At the present moment the Falls of Niagara are being utilised in this way. But apparently electricity is capable of producing food substances in a much more direct way than this. Given carbon, hydrogen, and oxygen in the simple association existing in carbonic acid gas and water, the current under certain conditions will bring about, according to recent researches, a re-arrangement of the elements until at length carbohydrates are obtained. It is stated that by merely passing a current of definite potential through soda water or water impregnated with carbonic acid gas a series of products is formed culminating in sugars. First of all is formed oxalic acid, then tartaric acid, next citric acid, until at five volts and three ampères grape sugar appears. If these things are true no more wonderful or astonishing discovery could be imagined. Carbonic acid gas and water are abundant enough throughout the whole world and to convert these simple substances into complex foodstuffs, for the supply of which we have to look to far countries, by simply manipulating them with the electric current, surely promises to bring about one of the greatest revolutions in the history of the world. But we have to reckon with nitrogen, the essential element of the proteid or flesh-forming portion of all food. As its Greek derivation implies (τὰ πρωτεῖα, pre-eminence), proteid is a vital constituent of all food, and it has been said "without proteid we die." Is it possible, then, that proteid will eventually be built up by electrical means in the same way as is carbohydrate? In such case plant life will no longer be indispensable to man. Though at present proteid cannot be constructed directly, yet the production of nitrate by electricity is a source of stimulus to the synthesising process of the plant and therefore electricity comes again to our aid in the production of food. As to the mineral salts of food, they again are essential; but then, of course, chemistry has long since furnished us with material for their production. It seems clear that the chemist and physicist are unfolding nature's ways with a rapidity which is startling considering that what they have already achieved amounts to saying that given an abundant supply of chalk, air, and water the food problem is solved. The ingredients of the formula are in truth plentiful enough, but what a dismal world when plant life is no longer necessary to the human race.

DOES MERCURY CAUSE TABES?

DR. PAUL COHN refers in the *Berliner Klinische Wochenschrift*, No. 10, 1903, to the question which is still regarded as debateable—viz., as to whether mercury administered for the treatment of syphilis is a likely agent in the production of tabes dorsalis. He gives an account of his investigations in regard to this point on 117 cases of tabes, comprising 86 males and 31 females. The histories of these patients were carefully inquired into as regards the date of syphilitic infection and the period, if any, through which they had undergone mercurial treatment. Of the 117 patients 43 males gave a distinct history of syphilitic infection; 15 of these had never been treated with mercury, while the remaining 28 patients stated that they took very small doses of the drug and only for short periods of time. In no case had a syphilitic patient undergone a thorough, prolonged, and systematic mercurial treatment for his illness. Of the 8 male tabetic patients 63 had thus never undergone mercurial treatment at all. Considering therefore the large proportion of the latter, and having regard also to the fact that the few patients who did undergo mercurial treatment took the drug in small quantities and only for brief periods, Dr. Cohn concludes that tabes dorsalis could not be regarded as due to the toxic or cumulative effect of mercury. Of the 31 female tabetic patients five only had been treated with mercury. The exact proportion of syphilitic cases among the women was difficult to ascertain, but the fact that symptoms of syphilis had been present in many of them without being suspected at the time was conclusively proved by careful inquiries into their history. Many of these suspected cases were characterised by the usual symptoms of syphilis, such as sore-throat, and occasionally also a roseolous rash was said to have developed, while still-births were noted to have been of frequent occurrence The total body of evidence collected from both male and female cases tended to support the conclusion that mercury was not a cause of tabes dorsalis. Among the patients there were a few who did not reveal signs, symptoms, or a past history of syphilis, but several of them, adds Dr. Cohn, had suffered from severe illnesses, such as typhoid fever and influenza, prior to the commencement of tabetic symptoms. Dr. Cohn therefore believes that while the predominant rôle in the production of tabes dorsalis must be assigned to syphilis other toxæmic agents (infective fevers) may also play a part in bringing about tabetiform degeneration of the spinal cord but that mercury plays no part in the production of tabes or in accelerating its course when established.

THE CHEMICAL CHANGES IN THE BLOOD IN CHLOROSIS.

AN interesting contribution to our knowledge of the chemical changes in the blood of chlorotics is given by Dr. Franz Erben of Vienna in the *Zeitschrift fur Klinische Medicin,* Band xlvii., Hefte 3 and 4. The blood of three chlorotic patients was examined by Hoppe-Seyler's method for organic substances and the ash was analysed according to Bunsen's method. Dr. Erben found in addition to the universally recognised reduction of the percentage of hæmoglobin, which in his cases ranged from 30 to 52 per cent. of the normal, that the fat in the serum was strikingly increased, which accords well with the tendency to the deposition of fat in chlorotic girls. The proportion of lecithin, on the other hand, was somewhat diminished in all three cases and the proteid substances in the two which were more severe were reduced about 1 per cent, the proportion of albumin to globulin being normal and the fibrin somewhat increased. As far as the inorganic constituents were concerned Dr. Erben found that the potassium, iron, and phosphoric acid were diminished and the calcium and magnesium were increased.

TREATMENT OF THE MORPHIA HABIT BY SUDDEN WITHDRAWAL OF THE DRUG.

IT has generally been held that in the treatment of patients suffering from the morphia habit abrupt withdrawal of the drug is liable to produce dangerous symptoms of collapse and physical prostration, and hence the commonest method adopted has been to diminish the habitual daily dose of the patient in such a manner that the quantity was reduced to zero in from two to three weeks' time. This method of "tapering off" the use of the drug has been recommended by eminent authorities, such as Mattison of Brooklyn and Erlenmeyer of Berlin. In the *New York Medical Record* of April 11th Dr. Margaret Halleck of the New York State Reformatory for Women gives an interesting account of the successful treatment of five female patients who were admitted to the institution for treatment of the morphia habit, the method adopted in each of these cases being that known as the "sudden withdrawal" of the drug. These patients were, however, given daily injections of other alkaloids to combat prostration and collapse and the results as recorded appear to have been uniformly successful "As each patient came under care," adds Dr. Halleck, "I endeavoured to win her confidence. ...... I told her frankly that no morphia would be administered but that she would not be allowed to suffer much" Personal interest was shown in every case and strong mental "suggestion" of improvement was freely used. The following two cases may be taken as typical of the methods of treatment followed and of the results obtained. Case 1 was that of a woman, aged 24 years. The morphia habit was contracted while she was under treatment for a broken leg. She finally took from six to ten grains of morphia daily, besides smoking a "dollar's worth of crude opium." On admission she suffered from sleeplessness and attacks of vomiting, her pupils were dilated, the extremities were cold and perspiring, she was aching all over and was in a very nervous condition. The following preparation was used for treatment—viz., $\frac{1}{30}$th of a grain of strychnine sulphate, a quarter of a grain of codeine sulphate, and $\frac{1}{200}$th of a grain of hyoscine hydrobromate in sterile aqueous solution. This was injected hypodermically every night with the suggestion that she would sleep well. Sleep improved day by day, the pain and attacks of vomiting disappeared, and at the end of a week there was marked improvement. The daily injection was then limited to strychnine only ($\frac{1}{30}$th of a grain) for another week, after which all medication was stopped. Her weight on admission was 99 pounds. In six months she had gained 30 pounds in weight. She remained in the institution for a year and then left quite recovered from the habit and has continued well since then without relapsing. Case 2 was that of a woman, aged 24 years, who was taught the use of morphia by an older woman. She had taken morphia hypodermically for seven years, her dose being eventually from 50 to 60 grains per diem. On admission she was very emaciated and weighed only 90 pounds. She was nervous and agitated, her pulse was slow, the pupils were dilated, and the bowels were constipated. Treatment similar to that adopted in Case 1 was followed with good results. Her appetite and sleep improved, she gained weight to the extent of 20 pounds in six weeks, and was discharged as recovered. Of the five patients whose histories are recorded two smoked opium for several years and the other three took morphia hypodermically or by the mouth. All these patients seemed to have lost their craving for the drug after having undergone treatment. The combination of strychnine, codeine, and hyoscine is highly recommended by Dr. Halleck for its excellent adjuvant effects in promoting the recovery of the patient and in obviating the physical prostration which would otherwise follow upon sudden withdrawal of the drug.

SUNDAY TESTING.

WE trust never to see Sunday abolished in general as a day of rest, but in these modern times it is perfectly obvious that it cannot be always a day of rest for everybody and therefore to some extent a breach of the Lord's Day Observance Act is of constant occurrence. The milkman must go his rounds on Sunday, a limited number of trains must be run, a single post at any rate must be collected, the gas-, electric-, and water-supplies must be maintained, and so on. But should the machinery be stopped on Sunday which controls the quality and purity of the food-, gas-, or water-supply? In an action heard in the Chancery Division this week a metropolitan gas company expressed the opinion that it should and refused to admit the gas examiners to the testing stations on Sundays. For 40 or 50 years, it was urged, the London County Council and its predecessors had tested only on week days and that put an interpretation on the Act which prevented the County Council from carrying out its duties on Sundays The County Council, however, concluded—and rightly, we think—that "it is never too late to mend" and recently had taken up the matter of testing the gas on Sundays. We do not understand the gas company's position, as surely it is just as important to have a pure and efficient gas-supply on Sunday as on any other day. Some years ago it was discovered that certain milkmen took advantage of the inspector appointed under the Sale of Food and Drugs Act taking his, no doubt well-earned "day of rest," for when samples were secured on a certain Sunday there was found to be a remarkable rise in the number of cases of adulteration. In some instances the extent to which watering was carried on was disgraceful. We trust also that samples of the metropolitan water-supplies are taken on Sunday, as any neglect of that matter on any single day might conceivably inflict on London a severe epidemic. In short, it is of the utmost importance that control should be exercised in regard to those public supplies which of necessity are maintained on Sunday. The fact that it is the official's day of rest has tempted the unscrupulous to do on that day what they dare not do on a week day. The words of Mr. Justice Joyce in the case of the gas company mentioned above, "that he did not even suspect that the legislature did not intend that which was provided by the Act—namely, that the testing should be daily and every day, without excepting Sunday in any way whatever"—should apply in every case where the purity and efficiency of a daily need are concerned. The public has a right to be protected on Sunday just as much as on any other day, and so someone must occasionally forego the day of rest, but, of course, he should be compensated.

THE FESTIVAL DINNER OF THE ROYAL MEDICAL BENEVOLENT COLLEGE.

WE understand that the festival dinner of the Royal Medical Benevolent College, at which His Royal Highness the Prince of Wales will be in the chair, bids fair to be a great success. Among the list of stewards occur the names of gentlemen important in such different walks of life as the Prime Minister, Prince Louis of Battenberg, Sir Thomas Bucknill, the Archbishop of Canterbury, Sir Michael Foster, Lord George Hamilton, Sir Trevor Lawrence, Lord Lister, Sir J. N. Lockyer, Field-Marshal Sir Henry Norman, and the Earl of Rosebery. We cannot find space to mention the names of the many well-known medical men who are supporting the Prince of Wales as stewards.

STRUCTURE OF THE CHIASMA IN THE RABBIT.

THE disposition of the fibres of the optic tracts and optic nerves in the chiasma in rabbits has lately been made the object of study by Dr. Burton D. Myers who has published his results in the *Archiv für Anatomie und Physiologie* of His and Engelmann.[1] The majority of the sections were so made as to include with the chiasma a portion of the optic nerves and of the optic tracts. Nearly all the sections were stained with Weigert's hæmatoxylin and preserved in alkaline Canada balsam and they were obtained from animals that were not more than 12 hours old. The following are the conclusions at which Dr. Myers has arrived. The decussation of the fibres of the optic tracts in the chiasma is only partial in the rabbit. The non-decussating fibres are few and do not form an isolated or separate tract. The decussation is formed by an interweaving of fasciculi and not of fibres, differing in this respect from the chiasma of the toad. In the rabbit vision is binocular. It is impossible, with the present methods of investigation, to estimate the number of fibres in the optic nerve with any degree of precision. In the caudal angle of the chiasma there is only one commissure, the commissura inferior, which was named by Hannover the "commissura arcuata posterior." This commissure in horizontal sections was named by Gudden "Meynert's commissure" and as seen in transverse sections the "commissura inferior," so that it appears that two names have been applied to the same fasciculus and, similarly, the term "Meynert's commissure" has been applied to two different fasciculi. In this inferior commissure or decussation medullated fibres begin to appear on the second day and the medullation is completed on the seventh day after birth. In the "decussatio subthalamica anterior" of Ganser, or "Forel's commissure," there are two independent fasciculi separated from each other by an interval of five days in the process of medullation of the fibres, although their course in the central grey substance differs to so slight an extent that they seem to constitute only one strand. The anterior or rostral portion ought to be named, says Dr. Myers, the "decussatio superior" in opposition to the "commissura" or "decussatio inferior," whilst the caudal or posterior part should henceforward be designated the "decussatio subthalamica anterior." The decussatio superior, which occupies a lateral position in the optic tract, first becomes medullated on the second day after birth. After crossing the median plane it probably terminates, as stated by Lenhossek, in the anterior nucleus of the optic ganglion. The decussatio subthalamica anterior, which embraces the fornix, presents medullated fibres on the seventh day. It probably ends in the nucleus supra-opticus (Lenhossek) of the basal optic ganglion. The optic nerve of the rabbit contains at the end of the first day comparatively few medullated fibres; on the fifth day there are several hundred fibres and all the fibres become medullated between the seventh and the ninth days.

CORONER'S INQUESTS AND REPORTS OF POST-MORTEM EXAMINATIONS.

AT the commencement of the year the following letter from the coroner of the borough of Cambridge was received by all the medical practitioners residing in his district:—

"*RE* INQUESTS."

15, Corn Exchange-street, Cambridge, Dec. 31st, 1902.

DEAR SIR,—Hitherto it has not been the practice for medical practitioners to send me the result of P.M. examinations. I have received verbal reports at the time of the inquests only. This has in some instances proved somewhat inconvenient. With the commencement of the New Year I therefore desire that a report be sent addressed so as to reach the police-station, say, two hours before the time appointed for the inquest. I am sure I need only express the wish and wherever possible it will be complied with.

Yours truly,
H. S. FRENCH.

In answer to this a reply was sent signed by the 23 practitioners concerned. The letter points out, firstly, that the coroner is not legally entitled to request either a written report of a post-mortem examination or that one should be delivered at any specified time or place Secondly, that compliance with the coroner's suggestion would cause a great increase of work and very likely great inconvenience to medical men. Thirdly, that such process as that contemplated in the coroner's letter was never contemplated when the present Coroners Act was passed and that the remuneration at that time fixed was only meant to be reasonable compensation for the definite services of medical witnesses required by the Act. The signatories of the letter, therefore, beg the coroner to understand that although they will use every endeavour to assist the coroner according to the terms of his letter, such increased work will be purely voluntary and therefore that inability to perform it on any occasion shall be without prejudice either to the practitioner or to his verbal evidence. So far as we can see the coroner is entirely in the wrong. He asks as a right what at the most he could only request as a favour. The Cambridge coroner is a solicitor as well as a coroner. We wonder what his answer would be were he to have a letter from a judge before whom he was about to appear requesting a complete note of his arguments in the forthcoming case to be sent to the court two hours before the commencement of the trial.

THE next general meeting of the Medico-Psychological Association of Great Britain and Ireland will be held at the Langham Hotel, Portland-place, London, W., on Friday, May 15th, at 4 P.M., under the presidency of Dr. J. Wiglesworth. An adjourned discussion will take place at four o'clock upon the two papers read before the last general meeting at the Derby County Asylum by Dr. Ernest W. White (the Care and Treatment of Persons of Unsound Mind in Private Houses and Nursing Homes) and by Dr. Outterson Wood (Lunacy and the Law). The members of the association will afterwards dine together at the Langham Hotel at 6.30 P.M.

AMONG the names of 15 candidates who were selected on April 30th by the council of the Royal Society to be recommended for election into the society appear those of Dr. W. M. Bayliss, Dr. S. M. Copeman, and Professor J. Symington. Dr. William Maddock Bayliss is Assistant Professor of Physiology at University College, London; Dr. Sydney Monckton Copeman is a Medical Inspector of the Local Government Board and is well known for his researches into the nature of variola and vaccinia; and Professor Johnson

---

[1] Anatomische Abtheilung, Hefte 5 and 6, 1902.

Symington is Professor of Anatomy at Queen's College, Belfast.

THE council of the Association of Public Vaccinators of England and Wales unanimously passed the following resolution at their meeting on May 1st and forwarded it to the President of the Local Government Board: "That this association would welcome the appointment of a departmental committee of the Local Government Board to inquire into the details of the working of the Vaccination Acts, 1867 to 1898, and would be prepared to give every possible assistance in any such inquiry."

WE understand that the complimentary dinner arranged by the London and Counties Medical Protection Society in honour of its president, Mr. Jonathan Hutchinson, has, at Mr. Hutchinson's request, been deferred from the beginning of May until July 23rd next. Medical men wishing to be present should communicate with the Secretary, London and Counties Medical Protection Society, 31, Craven-street, Strand, London, W.C. The price of the dinner tickets, exclusive of wine, is 7*s.* 6*d.*

A COURSE of 12 lectures in Experimental Pathology (the Gordon Lectures) will be delivered at Guy's Hospital Medical School during the summer session on Thursdays at 4 P.M. in the Physiological Theatre by Dr. E. W. Ainley Walker, the Gordon lecturer. The first lecture was delivered on Thursday, May 7th. These lectures are open to students from any of the medical schools of the University of London and to members of the medical profession.

AT the meeting of the Grand Lodge of English Freemasons held at Freemasons' Hall, Great Queen-street, London, W.C., on Wednesday, April 29th, among the Grand Officers appointed for the ensuing year by the M.W. Grand Master, H.R.H. the Duke of Connaught and Strathearn, was Mr. J. Ernest Lane, F.R.C.S., P.M. of the Sancta Maria Lodge (St. Mary's Hospital) who was appointed to the office of Senior Grand Deacon.

A MEETING of the Childhood Society will, by permission of Lord Egerton of Tatton, be held at 7, St. James's-square, London, S.W., on Monday, May 11th, at 3 30 P.M., when an address will be delivered by Professor John Edgar, Professor of Education, St. Andrews University, on the Universities and the Scientific Study of Children, with Special Reference to the Teaching Profession.

A MEETING will be held at the Polyclinic, 22, Chenies-street, Gower-street, London, W.C., on Friday, May 15th, at 2.30 P.M., when Mr. Jonathan Hutchinson will report the results of his recent tour in India for the investigation of leprosy. Discussion will be invited and the Right Hon. Lord George F. Hamilton, P.C., M.P., Secretary of State for India, has consented to take the chair.

SIR FRANCIS LAKING, Bart., G.C.V.O., who accompanied His Majesty the King on his recent tour, was appointed by M. Loubet, the President of the French Republic, a Commander of the Legion of Honour, having previously been appointed by the King of Italy a Grand Cordon of the Order of the Crown of Italy.

THE first meeting of the Central Midwives Board has been held, at which progress, we understand, was made in the drafting of the rules under Section 3, Clause 1, of the Act.

THE annual meeting and May dinner of the Aberdeen University Club (London) will be held in the Trocadéro Restaurant on Wednesday, May 20th, at 7 P.M., Mr. James Cantlie in the chair. Members desiring to be present are requested to communicate with the honorary secretaries, Dr. James Galloway and Dr. J. Malcolm Bulloch, at 54, Harley-street, W.

THE Lord Mayor's committee of inquiry, after considering the report of a sub-committee appointed to investigate the pecuniary management of St. Bartholomew's Hospital, has unanimously resolved that the governors of the hospital are justified in appealing to the public for funds to utilise the land acquired from Christ's Hospital.

THE annual general meeting of the Medical Defence Union will be held on Thursday, May 21st, at 5 P.M., at the registered offices, 4, Trafalgar-square, W.C.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

CONFERENCE OF THE CLERGY AND MINISTERS OF RELIGION.

ON Thursday, April 30th, in the saloon of the Mansion House a conference of the clergy and ministers of religion of all denominations was held under the presidency of the Right Hon. Sir MARCUS SAMUEL, Lord Mayor of London and treasurer of the Fund, for the purpose of discussing the best means of increasing the collections on Hospital Sunday.

The LORD MAYOR, in opening the proceedings, referred to the forthcoming visit of the King and Queen to St Paul's Cathedral. He said that when the highest in the land marked their approbation of the objects of the Fund in such a manner at what must be some sacrifice to themselves by travelling a considerable distance from their home he hoped that their kindly interest and the force of their example would bear such fruit as would enable a record collection to be made in 1903.

Archdeacon SINCLAIR said that the present conference was the result of a similar conference which took place at his house with the object of seeing whether it was possible to do anything to stimulate the clergy of London to make greater efforts in connexion with Hospital Sunday. At St. Paul's Cathedral the collections used to be very small but a former Lord Mayor wrote a letter to all the men of business in St. Paul's Churchyard and the neighbourhood and the result was a very substantial increase in the collection at St. Paul's.

The Rev. Canon FLEMING said that he was truly glad and he thought it was a very happy omen that the Lord Mayor had summoned them to a conference. They stood on the eve of a most important year for hospitals. The visit of the King and Queen to St. Paul's Cathedral was one of the great starting points for effort this year. Some years ago his friend Dr. Forrest, then vicar of St. Jude's, South Kensington, and now Dean of Worcester, said to him, "Fleming, how is it that you get that money? I will beat you next year," and he did beat him That was exactly the sort of rivalry that he had come to promote. It was a holy rivalry, free from all jealousy, in the cause of God's sick poor in our hospitals. His method was simply one of organisation. He had a letter asking for help largely printed and every one of his congregation besides those interested in the work of his church received one, while the same letter was for three weeks plentifully distributed in the pews of the church. He also gave a paper to every child in his Sunday school which stated: "Your teacher will be happy to receive any sum that your parents may intrust to you for the sick poor in our hospitals on Sunday next, which will be added to the church collection," and in this way he never got less than £10. It would be a most happy departure if all the churches would bring their Sunday schools in this way into closer touch with the work of the Fund. Then as to personal correspondence. He wrote something over 200 personal letters to the wealthiest people in his church. It would not do to have typewriting. The letters generally ran something like this: "Dear Sir or Dear (putting in the name according to the degree of intimacy with the recipient).—Should anything prevent you from being present on Hospital Sunday, June (here insert date), I shall be happy to receive any thank offering you may intrust to my hands for the sick poor in the hospitals." Experience proved that in all churches the congregations when asked readily supported the Fund, and as all creeds so gladly united all ministers should lead the way in their own congregations

The Rev. Prebendary RIDGEWAY said that his experience was very much the same as that of Canon Fleming. It was the personal letter which made the congregation feel that the Hospital Sunday Fund was something in which they must take a personal part. He sent letters to all sorts of people in the parish. If at one time it was desirable to direct the attention of absentees from church on Hospital Sunday still more was it so now. "Week-ends" were an important factor in London life which was very seriously affecting London churches. "Week-ends" meant people being out of town and away from their proper place on Sunday and the only way to get contributions from those people was to bombard them before Hospital Sunday, reminding them that being out of town did not excuse them from supporting the hospitals.

The Rev. C. H. GRUNDY said that some congregations had the idea that a small collection would not look well or be acceptable. Every congregation must make its collection proportionate to that congregation and the collection should be adequate to the neighbourhood. This applied to the congregation outside as well as in the church.

Dr. ADLER said that after what had been said he was sure that the ministers of his synagogues would not content themselves with a formal invitation to the worshippers to subscribe, but would send a few lines signed by themselves asking for subscriptions in the event of the worshippers' absence to be sent to the ministers.

Monsignor POYER said that he would have great pleasure in conveying all the suggestions that had been made to Cardinal Vaughan who, he felt sure, would at once commence to organise greater efforts than had been made hitherto. With regard to the organisation of ladies he would have much pleasure in putting the ladies of charity at the disposal of the Fund.

The Rev. CHARLES VOYSEY said that when he contemplated the vast wealth of the metropolis and compared the annual contribution to the Fund—some £50,000 or £60,000 at the most—and remembered that this was not an uncommon price to pay for a picture, no words could express his astonishment or shame. Why were these things so? The rich people who gave little or nothing to the Fund were generally too poor to give. They lived up to their incomes or spent their surplus in luxury and pleasure. They must convert these people from selfishness to love and open their eyes to see that what they called their wealth belonged to their Maker. Until they got at their hearts they could not get at their pockets. He threw out this hint to his clerical brethren, some of whom had wealthy persons in their congregations who did not do their duty. Take away extravagant and outlandish amusements, costly entertainments and ceremonies, and above all ornamental dress, and the vast sums now wasted upon them would be available for charity and they would never again have to go begging for Hospital Sunday. He had never done such a thing in his life as preach a charity sermon.

Mr. RICHARD B. MARTIN, M.P., appealed to all ministers to give the Fund the whole of their collections. A large sum of money was spent in advertising Hospital Sunday and it was unfair to the Fund not to give it the whole sum collected.

The Rev. RAVENSCROFT STEWART proposed a vote of thanks to the Lord Mayor which was seconded by the Rev. S. MARTYN BARDSLEY and supported by the Rev. Prebendary COVINGTON. The vote was carried unanimously.

In his reply Sir MARCUS SAMUEL said that the interesting discussion to which he had listened that day was a complete justification for acceding to the request of Sir Edmund Hay Currie that a conference should be held in the Mansion House. It was, of course, only a preliminary of that great meeting which was arranged for June 8th when his Grace the Archbishop of Canterbury, Sir Frederick Treves, and Sir Douglas Powell, all able speakers and attractive orators, would address the meeting. The Lord Mayor's life of office was a continuous one of appeals. Nevertheless he intended sending out 5000 letters to the home counties, for he found that out of the 100,000 patients in the hospitals of London 25,000 came from the counties outside London. There was thus a claim upon those districts. If the prediction that this year would be a record one in the history of the Fund should prove true it would be one of the greatest joys of his mayoralty.

MEDICINE AND THE LAW.

Seven Years' Penal Servitude for an Abortionist.

AT Manchester assizes on April 24th Mr. Justice Lawrance sentenced to seven years' penal servitude a woman who had practised for 15 years as a midwife and had performed an illegal operation upon her own daughter who had since died from the blood poisoning set up. In this case the prisoner appears to have been very unwilling at first to do what her daughter asked her to do and to have yielded only after considerable pressure. No doubt this circumstance and the fact that she had suffered the grief of seeing her child die as the result of her act influenced the jury to return a verdict of "Manslaughter" with a strong recommendation to mercy instead of the verdict of "Wilful murder" which would presumably have been in accordance with the law and the facts. The sentence of seven years' penal servitude will be sufficient to act as a deterrent to others and taking into consideration the temptation to which the prisoner was subjected it may no doubt be regarded as adequate.

Surgery and Workmen's Compensation.

In three cases under the Workmen's Compensation Acts which have recently been argued upon appeal an interesting question has been raised as to the liability of the employer to continue to pay compensation for injuries suffered in the course of his employment where the continuance of the disablement is, or may be, due to the workman's refusal to submit to surgical treatment. The first of these cases[1] was heard in Scotland in last December. The employers sought to exercise the right given to them by the Act to have the payments which they had been ordered to make reviewed in order that they might be discontinued. They had required their workman, as they were entitled to do under the Act, to submit himself to a medical practitioner for examination and this gentleman, Mr. Thomas Kennedy Dalziel of Glasgow, had reported with regard to an injury to the right ankle of the workman caused by it being struck with a piece of iron: "The present condition of the foot is due to the varicose condition of his veins together with want of suitable exercise; the stiffness of the ankle is due to persistent malposition and might well have been rectified long ago by suitable massage and movement. I do not think that the blow on the outer side of the ankle received over three years ago can now be considered as the cause of his defective limb." It was found as a fact by the sheriff substitute that the workman had not used his foot to the extent to which he had been recommended to do so and had not exercised it by passive movements at all and that he had refused to submit himself to surgical treatment at Paisley Infirmary where arrangements had been made for him. The medical referee to whom the matter was submitted, owing to the evidence of Mr. Dalziel being dissented from by other witnesses, reported that "the present condition of the ankle is due not to the accident but to want of proper treatment since the accident took place." The sheriff, with these materials before him, was of opinion that the employers were not bound to continue their weekly payments and upon appeal the court upheld his decision, Lord Adam, who delivered judgment, saying in the course of doing so: "I am far from thinking that in every case a workman who has been incapacitated from work by an accident is bound to submit to any medical or surgical treatment that may be proposed, under the penalty, if he refuses, of forfeiting his right to his weekly payments. It is easy to suppose a case where a more or less serious operation is proposed with more or less probability of a successful cure, and in such a case I think it would be out of the question to say that the workman is bound to submit to it. But that is not the kind of case we have to deal with. In this particular case the injury was comparatively slight and the treatment proposed simple and common and brought within his reach and the benefit which would have resulted therefrom not doubtful. I think it was such treatment as any reasonable man would have adopted."

In the second case referred to,[2] which like the first was argued in the Scotch courts, the workman's thumb had been injured and had been amputated at the metacarpal joint. He still suffered pain after this and was prevented from doing his work at a coalpit where he had to shovel coal and to pull levers at a washing machine, and a further operation on the thumb-joint took place at the Royal Infirmary, Glasgow. In spite of this he continued unable to work; a third operation had been advised but he refused to undergo it. The findings of fact by the sheriff substitute as to the matters immediately in issue were that in spite of the two operations the workman still "suffered pain and was incapacitated from work in consequence of the adhesion of the skin to the stump. That this was due either to the defective performance of the operation in June or to some neglect in attending to the hand thereafter. That the appellant was examined on Sept 21st, 1901, and advised that he should undergo another operation, which would in all probability remove the sensitiveness of the injured part and enable him *to earn wages as before, or at least to earn more than he is* able to do now. That the operation so advised is a simple operation, not attended with serious risk or pain, and is such as a reasonable man not claiming compensation or damages would for his own advantage or comfort elect to undergo." In this instance again the court practically upheld the decision of the sheriff substitute, for it caused the payments to be reduced to 1*d.* a week until further order. One judge, however (Lord Young), dissented, saying that no case had been cited or suggested in which it had been held that a workman must submit to a surgical operation before he could be found entitled to the benefits of the Act and he added that it was not suggested that there was anything beyond an honest shrinking from a surgical operation by a man who had already submitted to two previous operations without the pain suffered by him being removed. Lord Trayner, who formed one of the majority, upon this pointed out that the finding of fact was that the proposed operation was not attended with serious risk or pain and observed that he should not himself hold a surgical operation to be compellable where risk to life or danger of permanent injury to health was present.

---

[1] Dowds v. Bennie and Son, 40 Scottish Law Reporter, 239.

[2] Anderson v. W. Baird and Co., Limited, 40 Scottish Law Reporter, 263.

The third case to which reference has been made[3] differed from the preceding two in that the county court judge at Birkenhead (His Honour Judge Bowen Rowlands, K.C.) had decided in favour of the injured workman who had refused to undergo some form of surgical treatment. In this case, as in the last one referred to, the injury affected the bone of a finger and the proposed surgical interference does not seem to have been of an obviously difficult [illegible]

Th [illegible]
an [illegible]
rec [illegible]

man's refusal was justified. He was upheld in this by the Court of Appeal without counsel for the respondent being called upon to argue. Perhaps a fuller report of the judgment delivered by the Master of the Rolls may be published in due course, as well as of the evidence which was given before the county court judge. The Master of the Rolls, according to the *Times* report of the case, said "that there was nothing in the Act which imposed upon the workman an obligation to submit to a surgical operation." Standing by itself without anything to limit its application this dictum scarcely appears to afford so useful a guide for judges on future occasions as those quoted above, emanating from the Scotch court. What is a "surgical operation" in the case of a finger crushed and lacerated by machinery? If the workman declining professional aid immediately after the accident prefers to bind up his hand with his pocket handkerchief, to go home and to remain there, is the employer to be liable to compensate him for the result of an injury thus treated, whatever that result may be, on the ground that he is not bound to submit to a "surgical operation"? Is the treatment immediately necessary in such a case less a "surgical operation" than that which may become desirable at a later stage? It is not stated in so many words in the Workmen's Compensation Act that the injured workman shall be required to undergo such treatment as a reasonable man would submit to who had no employer to compensate him, but unless he is so required considerable injustice may be done to those [illegible] onsible for his disablement [illegible] have gone into the matter [illegible] suggested rules which are consistent with good sense and with justice to both parties.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on April 30th, Sir WILLIAM SELBY CHURCH, Bart., K.C.B., the President, being in the chair.

The following gentlemen, having passed the required examination, were admitted as Members of the College: Dr. Emil Paul Baumann, Dr. Robert Alfred Bolam, Dr. Edward Alfred Gates, Dr. John Hay, Dr. George Lucas Pardington, Dr. Llewellyn Caractacus Powell Phillips, and Dr. James Hutchinson Swanton.

Licences to practise were granted to 109 gentlemen who had passed the necessary examinations.

The following Members were elected Fellows of the College: Dr. Arthur Philip Beddard, Dr. Edmund Cautley, Dr. James Stansfield Collier, Dr. Bertrand Edward Dawson, Dr. Edwin Goodall, Dr. William Gordon, Dr. Alfred Milne Gossage, Dr. George Francis Angelo Harris, Dr. Laurence Humphry, Dr. Robert Hutchison, Dr. James Alexander Lindsay, Dr. Alexander Morison, Dr. Frederick John Poynton, Dr. George Alexander Sutherland, Dr. Walter William Hunt Tate, and Dr. StClair Thomson.

The PRESIDENT announced that the title of the Bradshaw Lecture to be delivered by Dr. E. F. Trevelyan this year would be Some Observations on Tuberculosis of the Nervous System.

Communications were received from (1) the Secretary of the Royal College of Surgeons of England reporting certain proceedings of the Council on April 2nd; and (2) the Sanitary Institute, inviting the College to send delegates to the annual congress to be held at Bradford from July 7th to 11th.

The following report was received from the Committee of Management:—

1. That the University of Cincinnati, United States, be added to the [illegible] of study.

2. The committee recommend that the following institution, which [illegible] ted on as [illegible] to the list [illegible] gland for [illegible]

Rossal, Fleetwood .... Rossal School.

3. The committee also recommend that the following clause and notes, having been adopted by the General Medical Council, be added to Section II. paragraph II. of the Regulations for the diploma in public health—viz.:—

> 4 (c) A sanitary staff officer of Royal Army Medical Corps having charge of an army corps, district, or command, recognised for this purpose by the General Medical Council.

[illegible]

Note to follow Clause 5:—

> *Note* (2). In the case of a medical officer of the Royal Army [illegible] cipal medical officer under [illegible] e has during a period of at [illegible] engaged in acquiring a [illegible] ministration in relation to [illegible] s evidence under *Rule* 4.

Dr. E. H. STARLING proposed the following motion which was seconded by Dr. J. KINGSTON FOWLER and carried:—

> That a committee be appointed to consider and report upon any alterations that may be desir [illegible] first conjoint examination. That [illegible] to confer with representatives of [illegible] the College of Surgeons be invited [illegible] this purpose.

The following Fellows were nominated to serve on the committee: Dr. E. H. Starling, Dr. F. T. Roberts, Dr. S. H. West, Dr. W. Pasteur, Dr. H. D. Rolleston, Dr. Norman Moore, and Dr. L. Shaw.

Dr. W. H. Allchin was re-elected as a representative of the College on the Senate of the University of London.

The Harveian Librarian (Dr. J. F. Payne) presented a list of books and other publications presented to the library during the past quarter and the thanks of the College be definitely proved that it did. He says: "If any part of the small intestine becomes unduly full the mesentery of that portion is stretched into an irregular wavy fan-shape and although the coil cannot be straightened it is made to assume a gentle curve at the distal end of its mesentery." And again further on he says, "If there are several distended ends together the gut at the end of each coil must bend sharply"—in other words, become kinked. What exactly he means by the distal end of the mesentery is not clear, for the whole length of the intestines are attached at the distal end of the mesentery; probably he means at the end of that particular coil of intestine, for he says, "the flow of the contents round this curve is easy." Unless Mr. Malcolm means that the fact that there are several distended coils determines the sharp bending the two statements are contradictory, for if distension causes a gentle curve that is a very different thing from a sharp bend. Distension to any great extent certainly causes a sharp bend and that whether the intestines are within or without the abdominal cavity so long as they are attached to the mesentery.

---

[3] Rothwell v. Davies, Times, April 27th, 1903.

Then Mr. Malcolm says that "when a piece of bowel which has not lost its peristaltic power distends it must push the ends of its coils against the boundaries of the peritoneal cavity formed by the abdominal walls and any piece of gut which is paralysed and inert must be bent at a sharp angle to an active piece of distended bowel with which it is continuous." But when a coil of bowel distends its ends will tend to kink exactly in proportion to the amount of distension, whether there are a few inches of inert gut at its end or not. It is not the inertia of the gut which determines the kinking, it is the degree of distension. If Mr. Malcolm means that if the few inches of inert gut occur, *not* where kinking from over-distension would under any circumstances occur but at the middle rather than at the end of a coil of intestine as it lies across the abdominal cavity, then I fail to see why it should kink at all. Mr. Malcolm also says that he cannot agree with me that the formation of a fistula is an unreasonable method of treatment if the nipped bowel is paralysed but the bowel above retains its peristaltic function. If Mr. Malcolm could prove that the paralysis of the few inches of nipped bowel did really cause an actual obstruction, then clearly the reasonable treatment would be to open the bowel above or resect the severely damaged part, but he does not prove it. My contention was that drainage of the intestine *as usually employed*, after the relief of a mechanical obstruction, in order to empty the paralysed and distended ends was an unreasonable proceeding.

I am, Sirs, yours faithfully,

Bristol, May 3rd, 1903. CHARLES A MORTON.

THE LONDON COUNTY COUNCIL AND THE APPOINTMENT OF OFFICIAL PATHOLOGISTS.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 2nd, p. 1251, is an annotation dealing with the meeting held at the Middlesex Hospital in reference to the London County Council and pathologists In regard to your remarks I should like to point out, first, that the meaning which you attach to "delegate" is a secondary one and true only in a limited sense The proper signification of "delegate" is wider and more general, though in some circles, as trades unions, &c., it has the acceptation you impart to it. Secondly, in regard to the voting The proceedings began by the chairman reading letters from King's College Hospital and Westminster Hospital which clearly stated the positions of both these corporations. My part in the business was therefore at an end and I remained only out of curiosity to hear what more could possibly be said on the subject.

After some discussion Dr. C. J. Cullingworth moved a harmless, innocuous resolution which allowed every body to do as it pleased. Up to this point I had no intention of taking part in the proceedings, but when a tyrannical and socialistic amendment was moved—an amendment which had the object of preventing individual action, was hostile to freedom of thought, and amounted to a declaration that certain institutions regarded themselves as the judges of what was right and proper for the rest of the profession—I felt that I ought to protest No objection was taken to my voting and in connexion therewith I may mention that the institutions located in Smithfield and the Borough had with a prudent thoughtfulness provided themselves with two representat apiece, though the votes of these extra *arbitri morum* disallowed. Thirdly, I think that if some 12 months ago Council had approached the profession informally jus ascertain the feeling of the latter in regard to this impor question before it was brought forward publicly m trouble might have been saved.

I am, Sirs, yours faithfully,

May 5th, 1903. R. G. HE

UNIVERSITY OF LONDON: SENATORI ELECTION.

To the Editors of THE LANCET.

SIRS,—It has not hitherto been the custom that candid for election to the Senate of the University of London sh issue an address to the members of Convocation, and we not apprehend that Sir Thomas Barlow will, in the pre instance, depart from so laudable a practice.

We therefore ask you to allow us to make known thro your journal that Sir Thomas Barlow, by his long and sustained service to the University continues, in our opin to merit the strong support of all those graduates who at heart the development of the University in the interest true education.—We are, Sirs, yours obediently,

May 6th, 1903.

THE ROYAL COLLEGE OF SURGEONS IRELAND.

To the Editors of THE LANCET.

SIRS,—It may be in the recollection of your readers some time ago correspondence of mine appeared in columns of THE LANCET relating to an examination the Fellowship of the above College. The circumstan were, to my mind, so unusual, from the fact m particularly that of 40 candidates examined at four exami tions 39 passed and that the College never denied hav broken its charters, by-laws, and Fellowship regulati at these examinations, that I felt no diffidence whate in giving publicity to the fact of my rejection. It further interest your readers to know that not hav sufficient confidence in the system of examination I refu a re-examination proffered me through my solicitor subsequently returned the certificate of primary exami tion which I had, in common with a few hundred ot Licentiates and third-year students, *obtained* without mination for £10 10*s*. on the occasion of Her late Majes visit to Ireland. This latter I did on the *ground* that I examined in a subject which according to its regulati the primary certificate exempted me *from*. The Coll whereupon acknowledged "the resignation" of my prim "examination" (*sic*). The President, Vice-*President*, Council subsequently refusing to return me my fees I s them in the Recorder's Court, Dublin, for their *recovery*.

Although the College had feed a strong Bar in the pers of the Solicitor-General for Ireland and Mr. W. G. Jeffers an eminent junior, no cross examination was made was any other defence attempted except the stock *one* a rejected candidate's "grievances." Indeed, the Colle frankly owned up to the violation of its charters by-laws through its secretary to council swearing that far as the Fellowship examination went it had been *doi* so for 14 years—that, in short, so many candidates n entered for this examination it would be *impossible* provide the "three or more" council witnesses requir Considering that each candidate paid £26 5*s*. for the privile of examination it apparently never occurred to the College pay the charter witnesses for attending to their char duties. The Recorder, while admitting the examination be "avoidable" one, referred the case without prejudice the superior courts.

To expend a few hundred pounds in endeavouring recover £26 5s is hardly a business transaction Some two months ago, however, I made further application to the College for particulars as to the amount I should now have to pay for a fresh Fellowship examination, whether I should receive consideration for the Primary Fellowship, subjects for which alone the College held my £10 10s as a clear profit, and also to be favoured with a copy of its recent by laws affecting the conduct of Fellowship examinations Except a letter in reply from its secretary, inclosing by the direction of the Council a copy of their Fellowship Regulations dated 1898, I was not given further information I presume therefore that should I care once more to undergo my experiences I must again pay up £26 5s, and that so far as a pronouncement on its mode of Fellowship examination goes the old order remains of examination without witnesses as was the case in the first instance The question what a chartered body is and why its by laws must be sanctioned by the Privy Council and why they then may be ignored by the corporate body most concerned will remain to me ever an interesting problem I am, Sirs, yours faithfully,

S WESLEY WILSON

April 20th 1903

AN OLD TITLE

To the Editors of THE LANCET

SIRS,—A book has just been published entitled, "Elementary Ophthalmic Optics" Will you kindly allow me a few lines to state that the author has appropriated the title of a book published for me in 1901 by Messrs J and A. Churchill and subsequently reviewed in your columns? I am, Sirs yours faithfully,

J HERBERT PARSONS.

May 1st 1903

⁂ As far as possible authors should avoid using titles belonging to other books, but this is not possible always in scientific literature "A System of Surgery" cannot be called by any other name if the contents fulfil the promise of that title, and the same must be said for example of "A Handbook of Clinical Medicine"—ED L

THE SEQUEL TO A "SUCCESSFUL" CASE OF EXCISION OF A CHRONIC GASTRIC ULCER

To the Editors of THE LANCET

SIRS,—In THE LANCET of Dec 13th, 1902 I published what I believed at that time to be a successful case of excision of a chronic gastric ulcer I regret to say that the patient has just died from malignant disease of the stomach and as the circumstances are of some interest perhaps you will allow me briefly to record them

The patient was a man aged (at death) 50 years After a history of pain after food and emaciation lasting about two and a half years I excised in November, 1901 a typical chronic ulcer from the anterior wall of the stomach At that time he weighed 6½ stones In the next six months he rapidly gained weight until he was 10½ stones in April 1902. He came to consult me again at the beginning of this year He had epigastric pain which came on always at night, and occasional vomiting after food His weight was 8 stones 2 pounds There was some induration in the region of the old scar I believed him to be suffering from a recurrence of the gastric ulcer and advised a gastro enterostomy He was reluctant to submit to further operation but came to me again in February At this time the area of resistance was much larger and more defined than it had been six weeks previously and the abdomen was opened on Feb 26th The entire stomach formed a hard pyriform tumour which felt quite solid and was uniformly affected from the cardiac end to the pylorus with what must have been malignant new growth At the time of this operation it was quite impossible to say from the view of the exterior of the stomach that this growth had begun at any particular spot. It resembled the diffuse carcinoma or "indiarubber bottle" stomach in the great and uniform thickening and in the preservation of the natural shape of the viscus There were several discrete enlarged hard glands in the gastro hepatic omentum He lived nine weeks after this time He had almost no pain and only occasional vomiting and was able to take light nourishment by the mouth until the day of his death The immediate causes of death seemed to be anæmia or inanition and toxæmia Dyspnœa, palpitation, and a gradually increasing drowsiness closed the scene.

I regard the case as one of chronic gastric ulcer which either became malignant before excision or else by its long continued irritation induced a diffuse malignant growth in the whole of the stomach The two and a half years' history of dyspepsia preceding the excision and the year's good health following it support the idea that the disease was in the first place inflammatory and only as a sequel malignant I am sorry to say that no post mortem examination could be obtained —I am Sirs, yours faithfully,

ERNEST W HEY GROVES, M D Lond

Kingswood Bristol May 2nd 1903

FREE ANTITOXIN TO THE MEDICAL PROFESSION.

To the Editors of THE LANCET

SIRS —In THE LANCET of April 4th, p 995, in the "Wales and Western Counties Notes" it is stated that the corporation of Hanley had decided to "supply antitoxin free of charge to medical practitioners in the town and to pay them a fee of 2s 6d in respect of the first case in a house (other than the patient) treated with antitoxin and 1s for each of the other inmates treated There is reason to believe that this is the first time an English sanitary authority has dealt with an outbreak of diphtheria by encouraging the use of antitoxin as a prophylactic" I am aware that in many districts and for several years past antitoxin has been distributed gratuitously by sanitary authorities but the novelty at Hanley appeared to be the payment of fees for treating contacts in infected houses and if this course has been adopted in Guernsey, in Camberwell or in Birmingham (though this is not quite clear from the communications you have received on the subject[1]) then the Hanley corporation cannot be credited with the initiation of the scheme

I quite admit that reading the last sentence of the paragraph quoted above by itself the interpretation put upon it by your correspondents is permissible

I am Sirs yours faithfully,

THE WRITER OF THE NOTE

May 2nd 1903

SUBSTITUTION IN THE SPIRIT TRADE

To the Editors of THE LANCET

SIRS —As a layman in a position to know intimately all that is going on I hope you will allow me to indorse everything stated in the annotation in THE LANCET of May 2nd p 1253 in regard to what you politely term the practice of substitution prevailing in the spirit trade I am, indeed, very pleased to see THE LANCET devoting its attention to this very important question which sooner or later, must be seriously taken in hand by the Government Indeed, in view of the evils which you have pointed out and which are bound to exist where the authorities allow anything to be sold in the form of spirit it passes comprehension that the Government should be so supine on the matter especially with the returns of lunacy and crime showing abnormal and alarming increase Quite recently I read that the Archdeacon of London attributed the increase of crime in Scotland to the bad drink sold to the people as substitutes for genuine malt whisky and brandy, and in the last annual report of the London County Council published a few weeks ago some facts and figures were given as to the increase of lunacy which are really startling The number of lunatics for which the Council is required to find accommodation has gradually increased from 10 356 in 1891 to 15 511 in 1901—i e, by 5 155 or about 50 per cent. in ten years And the report adds that drink and domestic and business troubles are the most common exciting causes But is it drink so much as bad drink? And in regard to this I can confirm all that you say as to the virulent maddening spirit that is sold to the public nowadays as whisky, especially, of course in the poorer districts And this is not the worst of it This spirit is sold in every fraudulent guise—as fine old Scotch fine old Highland, &c. When the Government allows without let or hindrance any stuff to be palmed off as the genuine article is it any wonder that substitution and fraud are rampant? Why go to Scotland for malt whisky, which will cost 3*s.* or 4*s.* a gallon, when I can freely import German spirit at 6*d.* a gallon, made from potatoes or any farmyard rubbish, and sell it as genuine Highland malt? Or if I should entertain any patriotic prejudice against the German article I can obtain in England spirit distilled from molasses and even have it bottled and labeled as finest old Scotch in a Government bonded warehouse under the very eyes of the Government officials. And all this "huge systematic fraud" is allowed while the poor grocer is at once pounced on should he sell, say, margarine (which is a wholesome substitute) for butter. Truly it does not lie with the whisky trade to complain of persecution or repression. It is, perhaps, the only trade in the country to-day in which the most elementary requirements of business can be safely ignored and fraudulent descriptions affixed, not only with impunity but under Government supervision, to what is sold to the public. And this applies not alone to obscure dealers but to some of the popular blends of the day which are sold under such terms as "Highland" or "malt" whisky when, perhaps, only about one third or so is Highland or malt, the rest being patent still spirit. But the stuff which is sent to our Colonies, to Australia, Canada, South Africa, &c., is usually much worse than that retained for consumption at home. I have seen spirit made up for the colonial market as Scotch and Irish whisky which makes me shudder to think of any human being drinking it. I do not object to people drinking patent still spirit if they want it, but what I do protest against is this spirit, or admixtures of it, being labeled as "Highland" or "malt" whisky and fraudulently sold as such. But from whatever aspect the question is regarded it is a monstrous state of things that the consumer of spirituous liquors has absolutely no protection as to the purity, genuineness, and wholesomeness of those liquors.

---

[1] THE LANCET April 25th p 1199 and May 2nd pp 1254 and 1260

I am, Sirs, yours faithfully,

May 4th, 1903. LUX.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Indian Research University near Bangalore.—The Improvement of Bangalore City.—A Scientific Research Department at Pusa.—The Plague Epidemic.—Nursing Arrangements in the Calcutta Hospitals.

THE site assigned in British India by the Mysore Government for the location of the Indian University of Research arising out of the offer of an endowment measures about 370 acres and is situated in the north-west of the Bangalore cantonment, about four miles beyond the municipal boundary. Besides this gift the Mysore Government has offered five lakhs for initial expenses. There is no doubt that the fixing of this site for this university will prove of great advantage to Bangalore and to the Mysore State, as it will become the great centre in India of scientific thought and research and a place of pilgrimage for all lovers of learning. Bangalore enjoys a climate suited to Europeans; its situation is central, and there are an abundance of available land and an unlimited supply of good water. The annual expenditure will be approximately £10,000, allowing salaries as follows: director, £1750; professor of chemistry, £1000; professor of experimental physics, £1000; professor of experimental biology, £1000; three assistant professors at from £450 to £600; secretary, from £150 to £200; glass expert, from £200 to £300; and six instructors at from £720 to £960 As to the future expansion of the University it is believed that further specialisation will be called for in each of the three departments of experimental science. In all probability there will be separate professors for pure chemistry, agricultural chemistry, metallurgy, general physics, electric engineering, animal physiology, vegetable physiology, and bacteriology.

A large project, estimated to cost nearly 18 lakhs, is now before the Government of India for the relief of the congested areas of the civil station of Bangalore on the lines adopted by the Mysore Government in extending the habitable areas of Bangalore native city. The present conditions of overcrowding are appalling. The provision of building sites on open and high ground which was made by the Mysore Government some time ago has been attended with excellent results. The civil station can do nothing without the help of the Government of India, as the municipal commissioners are already suffering from a depleted exchequer and are engaged on drainage works and an extension of the water-supply.

The Government of India is now working out the details connected with the Scientific Research Department which will be presently started at Pusa. The whole scheme will then be submitted for the Secretary of State's approval and sanction. It is probable that several European officers will be appointed to Pusa if the Government of India's suggestions are approved. No details, however, can be published at present.

The unprecedented total of 34,110 plague deaths recorded for the week ending April 4th has been followed by a sharp decline. For the past week only 27,787 deaths have been returned. In the corresponding week of last year there were 24,380 deaths. The Easter holidays and the great Mahomedan Mohurram festival may account for the great reduction officially returned. The decreased mortality has occurred in the Bombay Presidency, in Bengal, and in the United Provinces, and both the cities of Bombay and Calcutta record a lower mortality. The few details published this week are: in the Punjab 13,225 deaths as against 14,604 last week, in the Bombay Presidency 4405 as agains 6098, in the United Provinces 3211 as against 5130, and i Bengal 2445 as against 3387. Calcutta showed 819 death as against 980, and Bombay about 1500 as against 1858 Karachi is still suffering severely, but the cities of Poona and Bangalore are now practically free.

The nursing arrangements for the principal hospitals in Calcutta have undergone thorough revision during the past year. The Calcutta Hospital Nurses' Institution since its foundation in 1859 had been managed by a committee of ladies who succeeded in raising about Rs.15,000 per annum, and the institution was subsidised by the Government. On late years a larger staff of nurses has been necessary and last year a new committee was formed in order to bring the public more into coöperation and to raise the amount of the funds. The ladies' committee continues the internal management of the nursing arrangements. There are about *100 nurses employed in the different Calcutta hospitals and* about one lakh of rupees is required yearly. The Government has increased its subsidy from Rs. 37,500 to Rs. 50,000 per annum. During the past year the new committee has succeeded in largely raising the income of the institution, but it appeals for more support from the native community seeing that more than half the beds in the Medical College and Eden Hospitals are occupied by Indian patients.

April 17th.

VITAL STATISTICS OF JAMAICA.—In his report for the year ended March 31st, 1902, Mr. S. P. Smeeton, the Registrar-General of Jamaica, states that the population of the island as estimated to the date mentioned was 770,242. The number of marriages registered in the year was 3202, giving a rate of 4·1 per 1000 persons living, the number and rate for the previous year having been 3221 and 4 2 respectively. The births registered in the year numbered 31,268, giving a birth-rate of 40·9 per 1000. Of these births 20,022 were illegitimate, so that the illegitimacy rate was 64 per cent. of the total births, being the highest proportion recorded in the office. The Registrar-General here remarks that this is a very unsatisfactory sign taken with the fact that the marriage-rate for the year was, with the exception of the year 1897–98, less than at any time in the past 23 years One of the tables shows that during the ten years 1892–1902 in the 14 Jamaica parishes the lowest illegitimacy rate was 49 6 per cent. of the total births in the parish of St. Andrew in 1892–93, whilst the highest rate was 75·7 per cent. of the total births in the parish of St. Thomas in 1901–02. The parish of St. Andrew *must* be the most moral portion of the island, for it is the only one in which the illegitimate births seem never to have exceeded 54·3 per cent of the total. The deaths recorded in the year numbered 16,756, giving a death-rate of 21 9 per 1000. With regard to the causes of death, the largest numbers entered under any two headings were 3327 returned as "fever (undistinguished)" and 2005 returned as "other ill defined and not specified causes." Under "miasmatic diseases" 33 deaths were attributed to measles, 156 to influenza, 71 to enteric fever, and 6 to yellow fever. Of the total deaths in the year 13,358 or 79·7 per cent., were registered without any medical testimony as to the cause of death being obtainable The names of four practitioners were added to the Jamaica Medical Register, two deaths occurred, and 128 names remained on the Register on March 31st, 1902.

THE FOURTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

(FROM OUR SPECIAL CORRESPONDENT.)

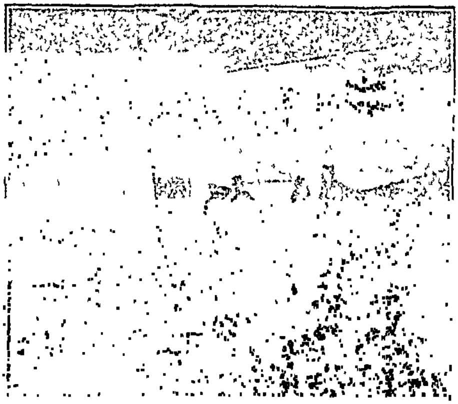
Madrid, May 1st.

As already mentioned in previous letters, much inevitable confusion prevailed on the morning of April 24th when the 16 sections met in the library and museum and attempted to get to work. To begin with, and in spite of posters and various other indications, it was no easy matter to find any one particular section, for the building is such a large one Three sections met in what might be described as in the basement, among exhibits of fossils, stuffed animals, elephants, crocodiles, tigers, crystals, minerals, and assorted butterflies Other sections met on the first or ground floor where there are appurtenances of the library, but the greater number were gathered together in the magnificent saloons devoted to the exhibition of modern paintings which are on the higher floor. A great number of chairs had been brought in and there was a long table provided in each section where the chairman or president sat, surrounded by the secretaries, presidents of honour, and other officials. But there were no press tables and such journalists as were present had to scribble as best they could on their knees. Each day a journal, the *Diario Oficial* of the Congress, was published, which for each section gave the names of the papers which were to be read. This, however, was but a vague indication, for so much depends on the length of the papers, the discussion that follows, and whether the authors happen to be present at the moment when they are called upon to speak. Not a little also depended on the fact whether the author and the chairman were able to understand each other. Through the difficulty of languages many mistakes were made, members going away when they ought to have remained or remaining when there was no necessity for doing so. One of the greatest hindrances, however, was due to the fact that in several cases it was impossible to reach one section without walking right across the rooms in which other sections met. This was particularly the case in the picture galleries and as there were not only the different sections to visit but also the magnificent pictures to look at the temptation to stroll from room to room was very great. Some of the pictures are justly celebrated, though others, it must be admitted, are scarcely worthy of being placed in such a magnificent gallery Nevertheless and considering that the museum was only concluded in 1896 the collections that have already been placed there are an honour to the country. But to admire these things was to neglect the Congress and to disturb somewhat the proceedings of the sections.

It must be confessed, however, that the work of the sections was often carried on before very small audiences The many empty chairs were silent witnesses to the number of desertions This is not surprising. The Congress being held at Madrid, the majority present were Spaniards and spoke in Spanish. There were very few foreign members who understood Spanish and the temptation was very strong for foreign members to get up and to look at the pictures instead of listening quietly to what was to them incomprehensible Add to this excursions to the Escorial and to Toledo and this supplies an ample explanation for the small number of foreigners who attended the meeting of the sections Others having papers in English or some language not likely to be understood by the majority of those present were sometimes content to get up, to bow, and as a matter of form to read the titles of their papers and then to present them to the chairman. Thus these papers will in any case be published in the report of the proceedings, where doubtless the foreign element will make a better show than it did in the sections and in person.

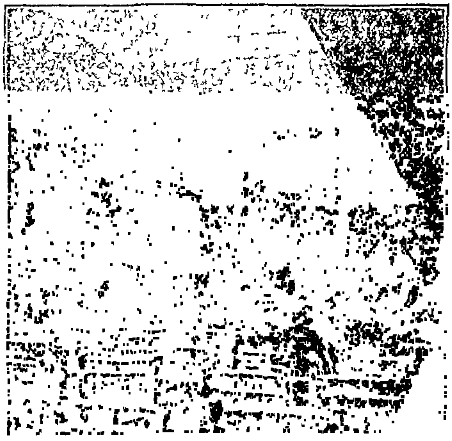
In regard to the pictures, some of them were not inappropriate. [illegible] butchery where surgical help wa [illegible] In the section of legal or foren [illegible] ge picture in which the figures are about life-size and which represents a duel. One of the adversaries has been shot while his enemy seems to be struck with remorse, a scene that suggests at once the need of prompt medical aid and of the intervention of the law. In the section of hygiene, on the other hand, there is a picture of young women enjoying a romp in an open field which is [illegible] on of medicine [illegible] in its centre [illegible] rs showed but little respect for the nude forms of the marble nymphs but placed hats and cloaks upon them in a most incongruous manner. The psychologists or neurologists secured a quieter though less attractive meeting place (Fig. 2). They raised around themselves a wall of glass cases containing precious manuscripts and the people who passed in and out of the room had to go by on the other side of this partition; however, few people attended this section. What with the insufficiency of light and the constant movement of the people present it was almost impossible to take a snapshot photograph of the sections. Nevertheless and in illustration of the above description I made a few attempts with more or less imperfect results.

FIG. 1.



Meeting of the Section of Legal Medicine.

FIG. 2.



Meeting of the Section of Neurology.

Madrid, May 2nd.

Apart from the ordinary sights, such as the magnificent collections of the old masters for which the picture galleries limited in number and easily arrived at. There were three which ought never to be omitted—namely, height, colour of the hair and eyes, and shape of the head. A uniform nomenclature ought to be adopted for the colour of the hair and eyes—namely, for the former fair, red, brown, and black and for the latter blue, grey of various shades (*verts, mélés ou gris*), brown, and black.

Dr. Double (Tours) read a paper on Variations in the Bones of the Human Skull. These variations might be divided into two principal classes—namely, (1) those which were reversive, theromorphic, and atavistic, or inherited; and (2) those which had no reversive character. A considerable list of reversive variations was enumerated affecting the occipital, parietal, frontal, ethmoid, sphenoid, and temporal bones. The variations devoid of reversive character were due, among other causes, to ossifications of the dura mater or fibrous ligaments, to the effects of pressure produced by vessels, nerves, meninges, tendons, and glands, to non-atavistic modifications of the form and size of the cranial bones and the appearance of supernumerary (Wormian) bones, to increase in the number of the normal points of ossification, to increased or diminished pressure of the brain and meninges, physiological or pathological dystrophy, and teratological variations.

Dr. Richard J. Anderson (Galway) read a paper on the Premaxilla in Apes, Bats, and Lemurs.

Dr. Unna (Hamburg) gave a demonstration (1) of Granoplasm and Spongioplasm (two protoplasmic substances) in the normal cells of different organs; and (2) of the "Schaumzellen" which were found in almost all œdemas and in many inflammations.

Physiology, Biological Physics, and Chemistry.

Dr. José Blanc y Benet (Barcelona) read a paper on Vegetable and Animal Life. He said that vegetative life had an existence in organised beings taken generally. Of all the differences between animals and plants the possession by animals of sensation and the power of voluntary movement and the absence of these faculties in plants had been in all ages considered as the most essential. In many cases, however, there were difficulties in deciding as to the presence or absence of these faculties. In the protozoa, for instance, no sensory organs had been discovered, neither could it be determined whether their movements were voluntary or not. There were some movements common both to living beings and to inorganic bodies, such movements being due to mechanical or physical causes, including endosmosis, capillarity, and Brownian movement. Other movements were due to the contractility of protoplasm and the phenomena presented by the sensitive plant and by insectivorous plants might be explained in this way: these movements were automatic and constant; they always repeated themselves in the same circumstances. Voluntary movements, on the other hand, presupposed spontaneity, knowledge, and choice. The difficulty of distinguishing between these different kinds of movement might be attributed to the imperfections of the methods of investigation. In conclusion, amœboid movements were discussed.

Dr. Agustin Murúa Valerdi read a paper on Organo-metalloid and Organo-metallic Medicines. In these preparations, he said, the chains of the organic molecules inclosed elements such as iodine, rubidium, zinc, arsenic, &c. He then proceeded to describe the preparation and properties of numerous compounds containing organically combined arsenic, especially cacodylic acid and cacodylates of metals, subjects upon which much work had been done in the chemical laboratory of the University of Madrid. He next engaged in a bio-chemical study of the therapeutic use of arsenic with especial reference to the views of Professor Gautier and to the properties of the glycero-phosphates which had some points of analogy to the arsenical compounds. His experiments on the toxicity of these substances were made in Dr. Ferran's Institute for Serum Treatment and Bacteriology in Barcelona. In conclusion Dr. Murúa gave a sketch of the literature of the organo-metallic compounds, including, in addition to those already mentioned, several preparations of phosphorus and silver.

Dr. Antonio Vidal (Buenos Ayres) read a paper on the Pathology of Heat-stroke. His principal observations were made during the "epidemic" of heat-stroke which occurred in Buenos Ayres and some other cities of the Argentine Republic in 1900. Dr. Vidal also read a paper on Biological Stereo-chemistry and Geometrical Conceptions of Space in their Biological Relations.

Dr. Richard J. Anderson (Galway) read a paper on Muscle Training or Moulding, at the outset of which he mentioned Sir Lauder Brunton's observation that the pose which was of so much significance in various mental states came to be of great service in supplying a key to the nerves that were concerned in some other peculiar conditions. Muscular action seemed to be the chief, if not the only, means by which animals first became acquainted with the phenomena of the external world. It was therefore important to consider how far this sense was independent of the other senses. Birds and reptiles probably derived little assistance from the senses of smell and taste There was early development of the sense of smell in mammals and of those of sight and hearing in birds, and in both (with some exceptions) the sense of touch was easily brought into action. The muscle sense was the chief and primary sense in all young mammals and in all birds probably. The other senses seemed chiefly to register the results.

Professor Juan Manuel Diaz Villar read a paper on experimentally produced pancreatic glycosuria. Complete removal of the pancreas in the dog produced hyperglycæmia and permanent glycosuria in from four to 24 hours after the operation, the animal ultimately dying from inanition. The operation was followed by loss of appetite and by uncontrollable vomiting; only an insignificant proportion of the food was digested, the greater part of it passing unchanged through the alimentary canal. Fat on being voided presented the same appearance as at the time of ingestion. The glycogen contained in the liver disappeared by conversion into sugar which passed into the blood and was wholly eliminated in the urine. The secretion of bile was diminished, the liver became pale, and bile pigment appeared in the urine. After eight days the appetite became voracious, the animal grew rapidly weaker, and its temperature fell to 35° C. Contrary to general opinion the liver took no part in the production of pancreatic diabetes; it gave up its stock of glycogen for conversion into sugar, but the hepatic cells were no longer capable of forming fresh quantities of this substance without the presence of the zymase which the pancreas supplied. The facts observed in experimentally produced pancreatic diabetes proved that the glycogenic process depended on the internal secretion of the pancreas. It therefore could hardly be doubted that the pathogeny of idiopathic diabetes was closely connected with more or less obvious changes in the pancreas.

General Pathology (including Pathological Anatomy and Bacteriology).

A paper by Dr. F. J. Poynton and Dr. Alexander Paine of London was communicated upon the Etiology of Rheumatic Fever. The work therein mentioned was a continuation and expansion of a research the results of which were published by Dr. Poynton and Dr. Paine in The Lancet.[1] That paper dealt with eight cases of rheumatic fever; the paper of which a *résumé* follows deals with 22 cases. The following is the abstract read at the Congress which was supplied for the use of members. The aim of this paper was to give in outline the result of a joint research by Dr. Poynton and Dr. Paine upon the cause of rheumatic fever. As a result of the investigation they concluded that a diplococcus was a cause of the disease. Before detailing the evidence in support of this conclusion they thought it advisable to state their conception of the disease which they were considering, a conception which was founded partly upon English clinical teaching. The early part of the paper was therefore concerned, firstly, with a clinical outline of rheumatic fever; secondly, with the reasons for the belief that it was a special disease; and thirdly, with reasons for the belief that it was an infective disease. They attached great importance to the clinical study of rheumatic fever, for this plainly showed that the disease was a widespread affection of many different organs and not a mere inflammation of the joints. If looked upon as a mere inflammation of the joints the characters which made the disease a special one would almost certainly be overlooked. The strong hereditary tendency, the grouping of the cardinal lesions, the especial frequency of inflammation of the heart, and the relapses were evidence in favour of the specific nature of the disease. Further, the constancy of the pathological lesions, the nature of which could usually be foretold from the clinical symptoms, pointed to the same conclusion. Granted that rheumatic fever was a special disease it was also clear that it was one of a group of closely allied conditions and on account of this they had felt that the postulates laid down by Koch must be rigorously satisfied before any bacterium could be claimed to be a cause of the disease They had isolated a diplococcus from 22 cases of rheumatic fever and had demonstrated it in the principal lesions They had grown it in pure culture and produced by intravenous inoculation into rabbits identical lesions from which in turn they had isolated the bacterium and in which they had demonstrated its presence They therefore held it to be a cause of the disease and did not believe up to the present that any other bacterium had been proved to be a cause The morphological and cultural characters were next described It was a minute diplococcus streptococcal in liquid media staphylococcal in arrangement on solid Acid milk and bouillon and blood agar were suitable media It could be cultivated aerobically and anaerobically The virulence appeared to be low and very difficult to raise but was constant for long periods on suitable media They knew of no specific test for the diplococcus, but did not think that for this reason it should be grouped with allied micrococci as a variation of a hypothetical primitive streptococcus It produced they held a special disease and was to this extent a special organism having possibly obtained this specificity by a process of evolution They alluded to the far reaching researches of Marmorek Aronson Fritz Meyer, and others on these difficult problems The diplococcus was, Dr Poynton and Dr Paine thought, the excitant of the disease heredity, cold damp over fatigue, &c , were predisposing factors to its activity in the tissues In conclusion they pointed out that the elucidation of rheumatic fever had been, and was the outcome of very many investigations In their previous writings they had quoted many names Klebs, Popoff and Leyden and Triboulet and Wassermann had described what they thought to be an identical diplococcus before they (the authors) had published any writings upon the subject but they thought that they had in this research proved the etiological relationship of this diplococcus to rheumatic fever

---

[1] The Lancet, Sept. 22nd, 1900, p. 861 et seq.

NEUROLOGY, MENTAL DISORDERS AND CRIMINAL ANTHROPOLOGY

Dr H GUTZMANN (Berlin) read a paper on Neurasthenia and Impairment of Speech the latter being classified as (1) loss of memory and loss of faculty of association of ideas (akataphasia akatagraphia and amnesia), and (2) spasm or ataxy of the organs concerned in voice production (lisping stammering, and speaking in a whisper) The first of these two improved under general treatment directed against the neurasthenia , the impairment of speech ought to be treated by special exercises

Dr FLETCHER BEA [illegible] paper on the Care and Treatment c [illegible] le said that although epilepsy ha [illegible] of Hippocrates it was only 14 years since the first establishment in England for the treatment of these patients was opened. In asylums or colonies of this kind two classes of patients have to be provided for—namely, sane epileptics and insane epileptics For the former there were an asylum at Maghull near Liverpool the Meath Home (for females) near Godalming and a colony at Chalfont, at which latter place a second colony was in cour e of formation The law relating to the care of epileptic and defective children in England was an obstacle to the creation of asylums for children but Dr Beach was hopeful that the enactments limiting the number which could be received in an asylum would be modified

Dr FRENKEL (Heiden, Switzerland), read a paper on the Efficacy of "Re education in the most Advanced Cases of Locomotor Ataxy

Dr MANUEL IGLESIAS Y DIAZ (Madrid) read a paper on Pseudo Criminal Lunatics in Spain meaning thereby persons who being already insane were guilty of legally punishable acts or omissions and persons who became insane either while before the courts or after conviction During the last five years there had been 472 cases in Spain—i.e , about 94 per annum and one in 192 441 of the population Biscaya was the province in which the proportion of these lunatics was highest—namely, one in 9442 of the population The usual age of these lunatics was from 20 to 40 years , most of them were of the labouring class , their offences were principally infliction of bodily injury, homicide, parricide discharging firearms threats, incendiarism and wilful damage About one fourth of them were given up to their friends as guilty of minor offences , the remainder were required by law to be kept in the ordinary lunatic asylums There were, however several objections to this practice and a much better arrangement would be to have lunacy pavilions attached to prisons

Dr MANUEL IGLESIAS Y DIAZ also read a paper on Insanities of Toxic and Infectious Origin the most important exciting causes being alcoholism and influenza

Dr L VON FRANKL HOCHWART (Vienna) read a paper on Pseudo sclerosis (Westphal Strumpell) giving the history of a case which he had observed for 11 years The patient a male died from cancer of the stomach at the age of 42 years At the necropsy the only discoverable lesion of the brain and spinal cord was the existence of a considerable number of granulations of Pacchioni Dr von Frankl Hochwart gave several reasons for dissenting from the opinion held by the school of Charcot that pseudo-sclerosis was a manifestation of hysteria Pseudo sclerosis naturally resembled multiple sclerosis in many respects but several symptoms of frequent occurrence in the latter were very rare in the former as for instance the diminution of the reflexes nystagmus, disorders of the senses of sight smell taste and hearing paralysis of the face and the velum palati and finally incontinence of urine and fæces On the other hand mental disorder was often very marked in pseudo sclerosis The differential diagnosis between pseudo sclerosis and diffuse sclerosis was then discussed

Dr VICENTE OTS (Madrid) read papers on (1) Loss of Will Power and of Female Modesty after Hypnotism , (2) the Diagnosis Prognosis and Treatment of Mental Disorders of Infectious Origin , (3) on the Relation of Atmospheric Humidity and General Paralysis , and (4) on the Mental Condition existing in Dementia Præcox.

Dr JERÓNIMO GALIANA (Madrid) read a paper on Insanities of Toxic and Infectious Origin dividing them into (1) inebriety affecting the mentally degenerate , and (2) mania associated with syphilis Mental degeneration was an important factor in the etiology of inebriety In some of the individuals belonging to this class alcohol produced the condition known as pathological intoxication in which the mental state of the victims approximated in some degree to that of epileptics In these cases terminal dementia appeared early and had the special characteristic that while the failure of mental power was well marked the bodily strength was fairly well preserved In ordinary drunkards the terminal dementia was late in appearing and was apt to be associated with a group of symptoms which somewhat resembled those of general paralysis and has been named alcoholic pseudo-paralysis With respect to the relation between insanity and syphilis Dr Galiana said that the syphilitic psychoses properly so called were always the result of specific cerebral lesions In these cases the dementia and the delirium had no distinctive characteristics and similarly with regard to the motor affections which were no more than ordinary manifestations of cerebral syphilis The motor affections might consist in paralysis convulsions trembling movements and impairment of the faculty of coordination The relations of syphilis to general paralysis deserved separate mention It was well known that a considerable proportion of general paralytics had been the subject of syphilis and Dr Galiana had seen many such cases He had, however also seen general paralytics who to judge from the available data had not suffered from syphilis and he had known one general paralytic who contracted syphilis when his cerebral disorder was already well developed, thereby demonstrating his freedom from syphilis during the onset of the paralysis Dr Galiana is therefore of opinion that general paralysis is not essentially a disease of syphilitic origin

PATHOLOGY

Dr JUAN MANUEL MARIANI (Madrid) communicated several papers to this section We give abstracts of two

Blisters in the treatment of pneumonia —Blisters produce local effects which are both decongestive and exudative. They bring about nervous reflexes which increase the amplitude of the respiratory wave They increase phagocytosis and in all probability the cantharidine which is absorbed acts directly upon the pneumococcus or else by stimulating phagocytosis it increases the defensive powers of the organism

The treatment of anæmia by enemata of blood —Blood injected into the intestine is almost totally absorbed petition to the public health committee of the Lancashire County Council asking that if a preservative is allowed to be used in potted shrimps the maximum amount to be so used should be determined by Act of Parliament. It appears that the recent trial in Manchester of a case commented on in THE LANCET of April 4th has "prejudicially affected the sale of the genuine freshly potted shrimps, thus depriving the fishermen at Morecambe and other places of a considerable source of revenue." The public health committee has recommended the county council to ask the County Councils' Association to bring before the Local Government Board "the desirability of that Board determining whether any preservative should be used in potting shrimps, and, if so, of Parliament fixing the maximum amount allowed to be used" and of providing a distinctive label so that a purchaser might know that he was not buying freshly potted shrimps. Hygiene and commerce are becoming closely intertwined.

Midwives and Infant Death Certification.

Referring to the above-mentioned subject once again, Mr. Aitken, the acting coroner for Manchester, continued on April 21st his inquiry into the certification of the death of infant children by midwives. He said that he had been furnished with figures showing that 338 stillborn children were buried in Philip's Park Cemetery during the last 12 months and that if the other Manchester cemeteries were credited with burials on the same basis it might be calculated that about 1500 stillborn children were buried in the course of the year. "We have not a single guarantee that every one of these has not lived," he said. The law put it into the power of an unscrupulous woman to declare children stillborn simply on her own certificate. Dr. J. Niven, in his report for 1900, had noted the fact that whether the country as a whole is taken or the city of Manchester there is a steady decrease in the birth-rate, whatever the fluctuations of the marriage-rate may be. And he goes on to say that "it would seem from the figures as if there were some causes at work producing a lower birth-rate other than variations in the prosperity of the community." Mr. Aitken said that, taking the number of stillborn children at 1500, they would be in the proportion of 1 in 12 to the registered births. The matter came before the parks and cemeteries committee of the corporation on May 1st, when Mr. Aitken's calculations were not accepted as accurate. The 338 interments of stillborn children in Philip's Park Cemetery were reduced by 10 and those at the Southern Cemetery were given as 63. "Under these circumstances, the committee concluded—the officials of the cemeteries agreeing—that there were not more than 500 burials of stillborn children at all the cemeteries in one year." The drop of two-thirds is pretty considerable but it may be feared that mathematical accuracy has not been attained and the number of stillborn—or so-called stillborn—children buried in the Manchester cemeteries is not known within somewhat wide limits. As to the 500 that the parks and cemeteries committee would allow—"the officials of the cemeteries agreeing"—the report concludes: "This, of course, is a large number." Many witnesses were examined by Mr. Aitken, but not on oath, one of whom produced her own certificate, but it was merely a statement that she had "attended lectures" Stricter supervision is desirable, for whether Mr. Aitken's estimate or that of the committee be correct, the number of stillbirths seems too high.

May 5th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool School of Tropical Medicine: the Expeditions to the Gold Coast and Sierra Leone.

DR M. LOGAN TAYLOR has just returned from taking charge of the expeditions of the Liverpool School of Tropical Medicine at the Gold Coast and Sierra Leone. Dr. Taylor was sent to the Gold Coast a year ago in consequence of some rather alarming rumours as to the health of Europeans in that colony. He then drew up a set of recommendations for the improvement of the sanitation in the town of Cape Coast Castle, which were taken in hand immediately by the Governor, Sir Matthew Nathan. Dr. Taylor returned to Cape Coast Castle in November last with instructions to investigate the causes of the ill health on the Gold Coast and also to assist the Government in carrying out the recommendations which were drawn up a year ago. Dr. Taylor's engagement with the Liverpool School terminated early in February, but he was retained some time longer by the Gold Coast Government until Mr. G. L. Barker, assistant colonial surgeon, could arrive in Cape Coast Castle. Mr. Barker worked with Dr. Taylor on his previous visit to Cape Coast Castle, and on Dr. Taylor's recommendation the governor sent him back to Cape Coast Castle, on his return from leave in March, to carry on the work there. In an interview in Liverpool Dr. Taylor stated that very effective steps were being taken by Sir Matthew Nathan to improve the sanitation of the principal towns on the Gold Coast—viz., Accra, Cape Coast Castle, and Sekondi—and that proper sanitary departments had been instituted in each of these towns for the special purpose of carrying out much needed reforms. Sir Matthew Nathan had gone into the whole matter most carefully with Dr. Taylor. The conditions of health on the Gold Coast and other West African colonies were always fluctuating, and while they might be comparatively good in one district on the other hand they might be very bad in others. Cases of blackwater fever, remittent fever, and dysentery were constantly occurring, especially in the rainy season. Dr. Taylor was very hopeful that in the towns, at any rate, the new steps which are now being taken would have the effect of minimising as far as possible the chances of illness. He spoke very highly of Sir Matthew Nathan's interest in the whole subject and determination to leave no stone unturned to bring about a better state of health on the Gold Coast. Whilst on this expedition Dr. Taylor took the opportunity of visiting Freetown, Sierra Leone, and of winding up the fifth expedition of the Liverpool School of Tropical Medicine, which has been in operation there for a year and nine months. The majority of the men connected with this expedition ceased work last August, but a gang of 12 men was kept on for experimental purposes in the Grassfield district until the end of March. Freetown was chosen as a suitable place for testing the value of Major Ross's discoveries. Dr. Taylor expressed himself entirely satisfied with the results of the experiments carried on there It must not be forgotten that the practical sanitary work undertaken by Dr. Taylor and his assistants was not intended to be of an everlasting nature or to vie with the work on similar lines by a practical engineer. The object of the expedition was to clear up the town at once in the best possible way with the money at its disposal and the Liverpool School of Tropical Medicine had never felt that it was its duty to make the work permanent or even to keep it in an efficient state from year to year. This was a duty devolving upon either the Colonial Government of Sierra Leone or the Freetown municipality. Dr. Taylor, however, stated that Sir Charles King-Harman was showing great interest in the whole question and he expressed confident hope that although the Liverpool School of Tropical Medicine was no longer going to continue the work of this expedition the money spent by the school would not be wasted, as the Government was fully alive to the advantages arising from practical action on the lines advocated by the school. £2000 had been set aside this year for drainage work in Freetown and the worst streets were being dealt with first. The new water-supply for Freetown was now nearing completion and it was expected that by this time next year the mountain railway would be finished and the bungalows for the European officials completed.

The Opening of the Johnston Laboratories at University College, Liverpool.

The Right Hon. Walter Long, M.P., the President of the Local Government Board, will on Saturday perform the interesting ceremony of opening the new laboratories at University College, Liverpool. The laboratories are the munificent gift of Mr. William Johnston of Liverpool and they will be entirely devoted to research work in biochemistry. The event is very justly looked upon in Liverpool as one of no small moment, as the Johnston laboratories are the first of their kind constructed in Great Britain. The opening ceremony will be graced by the presence of several distinguished scientists from the continent, notably from France, Germany, Italy, and the United States of America, as well as by that of eminent visitors from this country. The new laboratory is a link in a continuous chain of developments. Together with the Thompson-Yates laboratories the new building will constitute and for the present complete the research department of the school of medicine. In the new department, which in buildings and equipment has cost upwards of £20 000, four professors will carry on their work. On the ground floor is the School of Tropical

Medicine, directed by Major Ronald Ross, F R S , late I M S There is here accommodation for 40 students Everything in relation both to tropical sanitation and to the study of malarial bacteria is at hand The professor himself is provided with a commodious room for his investigations The students who will work in this department are those who are specialising in tropical medicine after having acquired the general principles of medical science On the first floor Dr A S F Grunbaum will have the oversight of a branch of research concerned more immediately with cancer and kindred diseases A feature of this department will be a set of apparatus combining all the latest applications of electricity to the cure of that disease As in the case of the School of Tropical Medicine the work will be in the main of a post graduate character The cancer research department owes its foundation to the recent donation of £10 000 by Mr T Sutton Timmis, the material for which will be chiefly supplied by the Royal Infirmary On the top floor Professor Benjamin Moore is to carry on a school of bio chemistry, devoted to the investigation of that still obscure subject the chemistry of the animal tissues The chair of bio chemistry is a new one to which Professor Benjamin Moore has been recently appointed In each case there is a professor s room overlooking the quadrangle. Space has been found in the basement for the department of animal pathology directed by Dr H E Annett It is interesting to note that in association with this work the college has at Runcorn a station for the supply of the vaccine of small pox and diphtheritic antitoxin Meanwhile the work carried on in the Thompson Yates laboratories by Professor Rubert W Boyce, F R S , and Professor C S Sherrington, F R S continues to grow There has been fitted up a power room unique of its kind The municipal bacteriological laboratory has also been organised here as a separate department In Brownlow street, by the side of the Hartley botanical laboratory, the sites are in preparation for the buildings to be occupied by echnics In Ashton ected by Professor Lodge, is advancing towards completion Midway between these points the commodious structure which is in the near future to shelter the medical school has advanced as far as the first storey Before long there will crown the summit of Brownlow Hill the finest and most complete group of research laboratories in the kingdom although the foundation of the University College dates only from the year 1881

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS)

Small-pox

AMONG the large towns of South Wales there are cases of small pox only in Pontypridd (where there is one patient) and in Cardiff where six cases were notified during the week ending May 2nd During April there were 13 cases in Cardiff and during March there were 19 , in the first two months of the year only one case was reported In Merthyr there has been only one case of the disease since the end of January and Swansea has been entirely free for the whole of

situated in an isolated position and has been converted into a temporary hospital

Diphtheria in the Neighbourhood of Bristol

For several years past Mr J O Heaven of Bristol the medical officer of health of Keynsham rural district, has insisted upon the necessity for a bacteriological examination of material taken from the nares as well as from the throats of persons suspected of having diphtheria In the Keynsham district during the year 1902 of 20 bacteriological examinations which were made diphtheria bacilli were found in the throat only in 13 instances in the nose only six times and once in both nose and throat These records which are contained in Mr Heaven s last annual report support his contention that if diphtheria were systematically and universally fought by bacteriological examination of the noses and throats of ' contacts with a view of detecting those who while apparently well yet carry bacilli in the nose or throat to the danger of the community, a *very great step would be taken towards checking the spread* of the disease It is to be regretted that in Barton Regis rural district which also adjoins the city of Bristol the council has decided to rescind a resolution adopted in 1901 empowering the medical officer of health, Dr Edward Crossman, to obtain at the cost of the council a bacteriological examination in suspected cases of diphtheria. The only apparent reason for taking this retrograde step appears to be that 65 per cent of the swabs sent for examination gave a negative result and in the opinion of one member of the council this was ' fooling money away " At the meeting of the council held on May 1st Dr Crossman reported a further outbreak of diphtheria and if the valuable assistance of bacteriological examinations is withheld from him a very grave responsibility will rest upon the council

Housing of the Working Classes

At the annual meeting of the Bristol Committee for Promoting the Better Housing of the Poor, held on April 30th, Mr Lewis Fry said that without waiting for legislation it was extremely important that the powers possessed by local authorities should be enforced with more activity and vigour than is the case at present especially in rural districts As a remedy for the overcrowding and bad condition of houses in towns Mr Fry advocated the cheapening of locomotion and the removal of large industrial undertakings into rural districts

Death of Mr William Hughes, M R C P Irel , M R C S Eng , L S A

The announcement of the sudden death of Mr William Hughes, on May 3rd came as a painful surprise not only *to* the medical profession of Cardiff but to the towns people generally, for during the past 30 years he has been one of the best known figures among those engaged at Cardiff Docks He was born in Pembrokeshire and was a brother of the late Professor Hughes of Lampeter College After studying at the Middlesex Hospital he became qualified when about 25 years of age as M R C S Eng and ten years later came to assist Mr Hallam M Dixon who was at that time medical superintendent of the Seamen s Hospital ship *Hamadryad* Before the end of 1873 Mr Dixon died and Mr Hughes was appointed as his successor, a position which he held at the time of his death In 1874 he took the diploma of L K Q C P Irel., and in 1886 was elected a Member of that College Mr Hughes was most devoted to his work and although he was anticipating with pleasurable feelings the removal of the hospital to the new buildings now being of the work which *Hamadryad* The very much attached kindly sympathetic is distinctly the poorer through his death He is survived by his widow and one son.

Royal Mineral Water Hospital Bath

The annual court of the governors of the Royal Mineral Water Hospital was held on May 1st The report stated that 1201 in patients had been admitted during the year ending April 30th 1903 Since March, 1900, there had been 112 soldiers admitted to the hospital suffering from illness contracted during the war in South Africa The financial statement showed that the income for the year amounted to £7180 The expenditure amounted to £6017, which includes £523 the final payment on account of the extensive sanitary improvements which have been recently carried out in the building

Sanitary Inspectors Association

The western branch of the Sanitary Inspectors Association held its annual meeting at Falmouth on April 25th, when Mr C O Bullmore medical officer of health of Falmouth, read an interesting paper on Light Mr H Kelway contributed Items from an Inspector s Notebook giving a *résumé* of sanitary improvement carried out in Falmouth during the past few years Mr Kelway stated that as a result of the house to house test of drains 90 per cent of the systems had been modernised , this was brought about with a minimum amount of friction legal proceedings having to be resorted to on only two occasions. The mayor (Dr W Banks) afterwards entertained the members of the association.

May 4th

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Outbreak of Small-pox in Dublin.

THE outbreak of small-pox in Dublin has not assumed serious dimensions, being practically confined to an infected area in the north, the most crowded district of the city. The fact, however, seems due rather to good fortune and to the labours of general practitioners in zealously revaccinating the citizens during the last two years than to any really intelligent precautions emanating from the corporation. The case of Mr. Peckin, a corporation official in connexion with the cleansing and disinfection of clothes department—who died from small-pox, unvaccinated, and after three days' illness—has already been noticed in THE LANCET. Dr. F. J. Dunne, in a letter to the guardians of the South Dublin union, reported the case of a man employed at or near the Isolation Hospital at the Pigeon House Fort who had not been vaccinated. The superintendent officer of public health mentioned that two workmen who came from England refused to be revaccinated. One of the guardians inquired why in such circumstances he was retained at the hospital to the obvious danger of his fellow labourers. Other somewhat similar cases have been reported. An evening paper has stated in a leading article that at a house-to-house visitation made by the health officers during the week ending May 2nd no less than nine cases of variola were discovered in the infected area. They had been concealed and one of them was convalescent presumably after three weeks' illness.

Belfast Board of Guardians.

At the usual meeting of the Belfast board of guardians held on April 28th a report from the infirmary committee was presented recommending that the guardians should hire a house in a suitable locality within a radius of six or seven miles of Belfast to accommodate from 20 to 30 consumptive patients in the early stage of the disease. There are five wards filled with consumptives and the number was rapidly rising from 200 to 280. Last year 1100 persons died from consumption in Belfast and the medical officer of health of Belfast estimated that at present 4500 people were suffering in that city from the disease. It was decided after discussion to send the report back to the committee for the purpose of ascertaining what action might be contemplated by the city corporation and to make such further recommendations as it might think fit.

The Irish Medical Association.

At a meeting of the North Down Branch of the Irish Medical Association, held on April 30th in the Medical Institute, Belfast, Dr. F. P. MacLaughlin of Strangford presiding, the following resolutions were unanimously passed :—

> That the annual holiday leave to infirmary, dispensary, workhouse, prison, and asylum medical officers be one month free of cost to them.
>
> That the salaries paid to medical officers of health are inadequate.
>
> That it be urged on the profession that no doctor should accept a dispensary appointment under £200 per annum or workhouse under £120.
>
> That no medical man should interfere with, or take any position rendered vacant by, any medical officer, on his resigning office with a view to obtaining a salary approved of by the Irish Medical Association.
>
> That no medical man should under any circumstances apply for or accept any medical appointment when the outgoing medical officer, if entitled to same, has without just cause been refused superannuation.
>
> That we object to the scale of fees under the Factory Acts and to the Acts making these compulsory on dispensary doctors.
>
> That a fee should be paid for the examination of harmless pauper lunatics.
>
> That the following should be the minimum fees for temporary duty :—Dispensaries, four guineas and workhouses three or three and a half guineas per week or one guinea each per day.
>
> That Sir Wm. Whitla be elected first president of the North Down Branch of the Association, with Dr. Olpherts as honorary secretary.

A motion was also passed congratulating Mr. J. P. O'Riordan of Rathcoole on his recent victory in the courts over both the Celbridge guardians and the Local Government Board. Votes of thanks were also passed to the professors of Queen's College, Belfast, the medical staff of the Royal Victoria Hospital, and the chairman.

Death of Mr. George Gray, M.D. R U.I., J.P.

I regret to announce the death of Dr. George Gray, J.P., which took place at his residence, Newcastle, co. Down. on April 27th, from heart disease and glycosuria. Dr. Gray was born at Sheepbridge in co. Down and was educated at Queen's College, Belfast, which he entered in 1862, and in which he was a medical scholar in sessions 1864–65 and 1865–66, when he graduated as an honours man in the late Queen's University. At the Royal Hospital, Belfast, he obtained the Charter's exhibition and the Malcolm exhibition. Thoroughly trained and equipped as a young medical man he began practice in Castlewellan and subsequently removed to Newcastle, co. Down, where he enjoyed a large and lucrative practice and was greatly beloved and respected by his patients. In 1896 he was elected President of the North of Ireland Branch of the British Medical Association, of which for many years he was treasurer. Dr. Gray, who was a justice of the peace for the county of Down, contributed several articles to the medical journals and was a most careful and highly educated medical practitioner. He was buried at Newcastle on May 1st amid many evidences of the esteem in which he had been held by all sections of the community.

May 5th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Death of Dr. Laborde.

THE Paris Academy of Medicine has sustained a severe loss by the death of Dr. Laborde who passed away recently at the age of 72 years after a very full and busy life. A born physiologist he was well known by his work. He took a particular interest in the study of the functions of the nervous system and some years ago he discovered a system of re-animating those apparently dead from asphyxia by means of rhythmical tractions of the tongue. This method has become widespread and made his name well known. Latterly he had been much to the fore on account of the prominent part which he took upon the alcohol question as debated in the recently held discussions at the academy. His death is universally regretted.

Ablation of both Uterus and Ovaries in Osteomalacia.

At the meeting of the Academy of Medicine held on April 14th M. Fochier of Lyons related the following case. The patient was a woman in the fourth month of pregnancy who suffered from osteomalacia and in whom death seemed very near. M. Fochier thereupon removed the uterus and the ovaries and two and a half months later the osteomalacia was considered as quite cured. The rapid amelioration which took place in this case led M. Fochier to propose ablation of the uterus and ovaries as the treatment of election in osteomalacia, even when pregnancy was not present. M. Guéniot, however, considered that so far as his own experience went it would suffice to do a Cæsarean operation to terminate the pregnancy in cases of osteomalacia. This would have the advantage of allowing the woman to become pregnant again.

Technique in Rhinoplasty.

At the same meeting of the Academy of Medicine M. Nélaton described a proceeding in the operation of rhinoplasty which consisted in using the cartilage of the eighth rib to form the foundation of the nose. The operation is done in two stages at an interval of two months. In the first stage the cartilage of the rib is taken and inserted under the skin of the forehead whence the flap for the new nose is to be taken. Two months later the skin flap fitted with the cartilaginous skeleton of the nose is turned down and fitted into place. In two cases M. Nélaton had obtained good results by this method.

The Prophylaxis of Tuberculosis in Prisons.

The Prisons Board has laid before the Academy of Medicine a scheme for the prevention of tuberculosis in prisons, based upon the use of spittoons. M. Landouzy approved of the provisions of the scheme except in so far as regarded the cleaning of the spittoons *in loco*. He further suggested the use of lysol in the spittoons.

May 6th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Parturition and Lesions of the Eye.

DR. SIDLER, lecturer *(privat-docent)* on ophthalmology at the University of Zürich, has lately published some cases of lesions of the eye of newly-born infants occurring during parturition. Such cases are scarcely mentioned in handbooks of ophthalmology or obstetrics, but they deserve mention as they have a medico-legal bearing and interest the medical practitioner. Dr. Sidler excludes all cases due to the pressure of midwifery forceps applied *sine arte;* these occur not so very rarely but are seldom published. Some cases are on record which took place during normal parturition. Bock lately referred to such a case where one eye was completely forced out through rupture of its muscles. Hofmann published a similar occurrence as far back as 1854. Retinal hæmorrhages occur with great frequency. Königstein observed them 29 times out of 281 cases and Schluch in 49 cases out of 150 (a percentage of 33). Dr. Sidler gives detailed descriptions of seven cases which he has had occasion to examine.

Pasteur Institute at Berne.

The anti-rabies institute at Berne organised by the Swiss Federal authorities under Professor Tavel some years ago has treated 31 cases during the year 1902. In 20 of these patients the diagnosis of rabies was based on the experimental investigations of this useful institution. In three cases the veterinary surgeon had diagnosed the disease and in seven cases rabies was suspected; in one instance preventive inoculation was performed. The results were very satisfactory as all the persons inoculated remained in good health and free from rabies. 27 persons came from the canton of Vaud (Lausanne, Vevey, and Tour de Peiltz) and the other four patients from Berne, Neufchâtel, and Tessin. Out of 15 dogs and three cats sent for investigation 12 dogs were proved to be suffering from rabies.

Small pox.

Owing to the strenuous efforts of the Swiss sanitary authorities there have for many years been only isolated cases of small-pox in Switzerland and epidemics of a dozen or so cases have never spread, although a great number of children are not vaccinated, since certain cantons have disregarded medical advice and done away with compulsory vaccination. The *vox populi* turned a public health question into a political one and voted that every Swiss should be free. When any case of small-pox occurs it means a great amount of work for the district medical officer (*Bezirksarzt*) and heavy expenses for the Confederation. The patient is immediately sent to the nearest small-pox hospital, the names and addresses of all the persons with whom he had been in contact for the previous fortnight are noted down, and these—often a couple of dozen people—are at once placed in isolation hospitals, where they remain for a fortnight, then the relatives of these isolated persons are visited every day in case they should show suspicious symptoms. Thus any single case of small-pox may cost the Swiss authorities £100 or more, as the isolated members of the community are paid their wages for the time during which they are isolated. A small focus of infection has suddenly turned up in Maamedorf with 16 cases, but every possible precaution having been taken it is hoped the infection will not spread. Delay in making the diagnosis was the reason of the spread of the small-pox in this instance.

Zurich, April 30th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Increase of the Medical Corps of the United States Navy.

THE Fifty-seventh Congress of the United States in its last session provided for an increase of 150 members in the medical corps of the navy, 25 of whom are to be appointed each calendar year for six years. The number of vacancies in this corps occurring from resignations, retirements, and casualties average about ten a year which, added to the 25 created by new legislation, makes 35 appointments open to young medical men yearly. These appointments are to be made in the grade of assistant surgeon and are within reach of any well-qualified physician between the ages of 21 and 30 years who is a citizen of the United States. The medical corps of the United States navy consists to-day of the following numbers and grades: one surgeon-general with the rank of rear-admiral; 15 medical directors with the rank of captain; 15 medical inspectors with the rank of commander; 85 surgeons with the rank of lieutenant commander; 23 passed assistant surgeons with the rank of lieutenant; 56 assistant surgeons with the rank of lieutenant, junior grade, with 152 vacancies. There are 27 vacancies in the grade of assistant surgeon for the year 1903. Assistant surgeons, after three years' service as such, will be eligible for promotion to the next higher grade. The pay ranges from assistant surgeons, at sea, $1650 (£330), on shore, $1402 50, (£280 10*s.*); to medical directors, at sea, $4500 (£900), on shore, $3825 (£765), with ample allowances when quarters are not furnished by the Government The pay of the surgeon-general is at sea and on shore $5500 (£1100). The prospects of promotion are good owing to the numerous vacancies in the grades of passed assistant surgeons and assistant surgeons.

Bills Relating to Medicine and Sanitation in New York State.

On April 21st the New York State Senate passed the last of the Child Labour Bills framed by the Child Labour Committee. It amends the penal code so as to provide penalties for false statements in connexion with the employment of children. On April 21st the New York State Senate passed Senator Plunkitt's Bill amending the New York City Charter with reference to the street-cleansing department. The New York State Nurses' Association met in Albany on April 21st. It discussed the Bill providing a board to examine and to license trained nurses in New York State which has passed both branches of the legislature. At the close of the afternoon session the delegates called on Governor Odell and requested him to sign the Bill. He said that the measure had not reached him but that when it did he would give it his earnest consideration. The Bill creating a commission to investigate the condition of the adult blind in New York State passed the Assembly on April 21st. Its chief object is to provide methods whereby the adult blind of the State may be taught trades.

Professor Mikulicz in America.

Dr. J. Mikulicz, the well-known professor of surgery of Breslau University, has been recently staying in New York. His object in coming to America is in response to an invitation to read a paper before the American Surgical Association at its annual meeting in Washington, D.C. Professor Mikulicz, on the invitation of Professor William M. Polk, dean of the Faculty of Cornell Medical College, held an operative clinic at Bellevue Hospital.

Laboratory Building to be erected in Manila.

A new building is planned in Manila to provide laboratory space for the chemical and biological laboratories and the serum institute. The building will be divided into 60 rooms [illegible] pitals, municipal physicians, board of health, police force, and other Government institutions as may have occasion for such services. As such work is quite extensive considerable space will be allowed for bacteriological diagnosis. The investigation of tropical diseases and the pathological changes brought about by them, both in human beings and in domestic animals, will require the construction of several rooms for the study of their causation and to accommodate pathology and physiology. The plans of the building have been drawn so as to accommodate all of the work within one building, one half of which will be occupied by the chemical and the other half by the biological laboratory. The capacity of the serum institute will be such as to supply the entire archipelago. Two houses for the accommodation of small animals are to be built in the rear of the laboratory building, one of which will be for the use of the laboratory proper and the other for the serum institute. An adequate library will be built in connexion with the laboratories. The building plans have reserved a space in a central location which will be capable of accommodating easily 30,000 volumes.

April 25th.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

British Medical Association: New Zealand Branch.

THE annual meeting of the New Zealand Branch of the British Medical Association was held at Nelson from

March 2nd to 7th, under the presidency of Dr. S. A. Gibbs of Nelson, there being present upwards of 30 medical practitioners from all parts of the colony. In the absence of Dr. D. Colquhoun of Dunedin, the retiring President, Dr. W. G. Collins of Wellington, took the chair and installed the President-elect. In commencing his address Dr. Gibbs referred to the loss which the medical profession had sustained by the deaths of Dr. G. Cleghorn (Wanganui), Dr. Deamer (Christchurch), and Mr. A. C. Milne (Woodville), and also by the removal of Dr. C. Graham Campbell of Christchurch, for many years the secretary of the branch, in which capacity his services had been of the utmost value. Dr. Gibbs then proceeded to discuss some of the difficulties surrounding the general practitioner in the ordinary routine of work, referring particularly to the great need of some provision for treatment of incipient mental disease.

The following papers were read during the week: Operation for Moveable Kidney (Dr. Collins, Wellington), a Peculiar Case of Inguinal Hernia (Dr. E. E. Porritt, Wanganui), Mouth Deformity in Early Childhood (Dr. Hatherly, Wanganui), a Case of Leucocythæmia (Dr. J. Mason, Wellington), Uric Acid in Relation to Disease and Easy Methods of Demonstrating its Presence (Dr. Mason), the Campaign against the Consumptive (Mr. Coker, Wellington), Collection and Storage of Rain for Household Purposes (Dr. F. I. De Lisle, Napier), Relation of the Profession to the Lay Press (Dr. W. Anderson, Blenheim), the Medical Profession in Relation to Climatology (Dr. J. Gunn, Kaikoura), New List of Diseases and Causes of Death (Dr. McAdam), Ventilation, More Ventilation for the Travelling Public (Dr. J. Hudson, Nelson), Human and Bovine Tuberculosis (Mr. Gilruth, chief government veterinarian), and a demonstration by Dr. J. P. Frengley of Nelson on Modern Sanitary Fitments, illustrated by models, diagrams, &c. The following motions were passed:—

> That this meeting respectfully urges the Government to place all the institutions connected with the treatment of mental and bodily diseases under one department and to make provision for advanced cases of tuberculosis by erecting annexes to our present hospitals.
>
> That this meeting wishes to draw the attention of the Government to the need of better ventilation on steamers and railway carriages and they would suggest that the regulations against overcrowding be strictly carried out.
>
> That in the opinion of this meeting the Government should compel the notification by the owner of all cases of diseased mammary gland in cows, the milk of which is used for human consumption.
>
> That this meeting strongly deprecates the attack which has been made upon the chief health officer and his assistants in Auckland while attempting to carry out the duties devolving upon them under the Public Health Act.
>
> The attention of the conference having been directed to the publication in various newspapers of the colony of a paragraph setting forth the astounding information that scarlet fever is not infectious during the stage of desquamation (peeling), it was unanimously resolved that, in the interests of the public health, the paragraph should be publicly contradicted as evidence is conclusive that scarlet fever is infectious during the whole course of the disease, including the peeling period.

A recent statement by Dr. Koch, that in his opinion bovine tuberculosis was not transmissible to the human being, was held to have been amply disproved by all the most eminent authorities. Numerous instances were given by the medical practitioners present of cases in which the disease had developed apparently from drinking the milk of tuberculous cows, the sufferers in some instances dying after a very short illness. The system of inspection of cattle and dairies which had been inaugurated by the Government would, it was hoped, be extended and made more regular. Animals proved to be diseased should, it was urged, be immediately slaughtered, and until it was possible to establish a more regular and more frequent inspection of dairies, if there was the slightest doubt of the purity of the milk it should be scalded.

Several very enjoyable social gatherings varied the business of the meeting, including garden parties, drives, picnics, a conversazione, and the annual dinner.

March 24th.

Obituary.

EDWARD MONRO SPOONER, M.D. ST. AND., M.R.C.S. ENG., L.S.A.

THE death of Dr. Edward Monro Spooner is announced after a short illness at Blandford, Dorset, on April 17th. Dr. Spooner was born in 1840 and was educated at Epsom College, the London Hospital, and University College. He took the L.S.A. in 1864, became M.R.C.S. Eng. in 1865, and in 1881 received the M.D. degree at St. Andrews University. He succeeded his father Dr. Edward Oke Spooner to a large and extensive practice at Blandford. He was surgeon to the Blandford Cottage Hospital, medical officer and public vaccinator to one of the districts of the union, certifying factory surgeon, and honorary assistant surgeon to the 1st V.B. Dorset Regiment. Dr. Spooner took a keen interest in his professional duties and was untiring in his devotion to his patients. He was a ready and witty speaker and was deservedly popular with his professional brethren and his fellow townsmen. His kindness of heart and genial manner endeared him to his patients and especially amongst the poor will his loss be deeply felt. He leaves a widow, one daughter, and two sons, the elder of whom is a member of the medical profession.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the First Examination of the Board at the April quarterly meeting of the examiners in the subjects indicated:—

Chemistry.—Edward Morison Adam, Charing Cross Hospital; Harold Wordsworth Leach Allott, University College, Sheffield; Raymond Ebenezer Apperly, Middlesex Hospital; Thomas Herbert Cecil Benians and Walter Joseph Berne, London Hospital; Robert Stanley Capon, University College, Liverpool; Bernard Arthur Cheadle, St. Th[illegible] Thomas Clarke and Edmund Victor [illegible] ege, Bristol; Gordon Comyn, King's [illegible] Leslie Councell and Llewellyn Etter [illegible] Liverpool; Hugh Galloway, Westmi[illegible] ohn Gillett, Guy's Hospital; William Edwin Haigh, Technical College, Bradford; Charles Arthur Hallett, Westminster Hospital; Alfred Hanau, St. Bartholomew's Hospital; Arthur Reginald Hardy and Sidney Harlock, [illegible] hnical Institute, Salford; [illegible] llege, Sheffield; Edward [illegible] James Eustace Jackson, [illegible] p, St. Mary's Hospital; John Alfred Laughton, Charing Cross Hospital; Christian Frederick Louis Leipoldt, Guy's Hospital; Raymond Gabriel Maglione, Owens College, Manchester; Alfred Cecil Martin, London Hospital; Philip Walter Mathew, Middlesex Hospital; Frederick [illegible] Reginald Mugliston, London [illegible] ollege, Leeds; George Frank [illegible] Rowland Mabbatt Peake, Middlesex Hospital; Charles James Meaburn Phillips, St. Thomas's Hospital; Charles Edwin Price, Guy's Hospital; Claud Mallinson Rigby, London Hospital; Alfred Basil R[illegible] London; Francis Charles Searle, St. [illegible] Richard William Starkie, Owens College, [illegible] Technical Institute, Salford; George Fre[illegible] College, Liverpool; John Nuthall Watso[illegible] Adolphus von Wertern [illegible] and Guy's Hospital; and David Ed[illegible] Cardiff.

Practical Pharmacy.—Ric[illegible] f Birmingham; Evelyn Addison [illegible] Hospital; Hugh Lawrie Askham, [illegible] d Bethell, B.A. Camb., Cambridge [illegible]; Bernard Richardson Billings, Lo[illegible] Bintcliffe, Owens College, Manchester; Frank Treadwell Boucher and Edmund Victor Connellan, University College, Bristol; Martin Binns Studer Button and George Martin Clowes, London Hospital; Herbert Hugh Blair Cunningham, St. Mary's Hospital; Charles Stuart Douglas, Owens College, Manchester; Mervyn Eager, King's College Hospital; John Jackson Whatley Evans, Westminster Hospital; Harold William Farebrother, Charing Cross Hospital; George Edward Ferguson and Stephen Field, St. Mary's Hospital; William James Fletcher, Owens College, Manchester; Charles Ashley Flintoff, Charing Cross Hospital; Edmund George Foote, Westminster Hospital; Harman John Howland Graves, L[illegible] Buskard Hambling, St. Bartholomew's [illegible] wynne Howell, St. Thomas's Hospit[illegible] Harold William Latham, London Ho[illegible] ick, University College, London; [illegible] College, Manchester; Mahmoud Maher, Cairo and Guy's Hospital; William Beare Martin, Owens College, Manchester; Herbert Edwin Middlebrooke, London Hospital; Brian Bentley Metcalfe, Charles Sculthorpe Morris, L.D.S. Eng., and Edward Haldane Paterson, Guy's Hospital; Robert Elliot Pitts and Timothy William Sexton, Middlesex Hospital; Reginald Reynolds, University College, Bristol; Arnold Shelley, B.A. Oxon., Oxford University and London Hospital; Thomas James Bell Thomas, St. Mary's Hospital; Richard James Campbell Thompson, St. Thomas's Hospital; Seth Tinsley, Yorkshire College, Leeds; Charles Weller, Birkbeck Institute; Hugh Wheelwright and Mathias Wilhelm Eberhard Widegren, St. Thomas's Hospital; Peter Bruce Whittington, London Hospital; Robert Horace Constable Owen Wisdom, Cambridge University and London Hospital; René William Louis Wood, Yorkshire College, Leeds; Walter James Wood, University College, London; and Fred Yates, St. Mungo's College, Glasgow.

Elementary Biology.—Edgar Cecil Banks and John William Bintcliffe, Owens College, Manchester; Henry Alfred Biden, King's College Hospital; Maurice Frederic Bliss, London Hospital; Owen

College Hospital; [illegible]

Charing Cross H[illegible]
Hancock, St. Bartholomew's Hospital; Joseph Cecil Harris, University of Birmingham; Samuel Richard Harrison, London Hospital; Philip Keith Hill, Yorkshire College, Leeds; Norman Stewart Hoare, St. Thomas's Hospital; Claud Anthony Holburn, University College, Sheffield; David McKenzie Hunt [illegible]

Tomlinson, University College, Bristol; Francis J.mes Tuckett, Birkbeck Institute; Gerald Douglas Hamilton Wallace, Charing [illegible] and George [illegible] n, Guy's [illegible]; Charles [illegible] University College, [illegible]

UNIVERSITY OF CAMBRIDGE.—On April 30th the following degrees were conferred:—

Doctor of Medicine.—J. G. Taylor, King's; A. C. Hill, Trinity; J. D. Sandilands, Trinity; W. M. Strong, Trinity; F. C. Shrubsall, Clare; and W. T. Mullings, Christ's.

Bachelor of Medicine and Bachelor of Surgery.—E. D. Macnamara, Peterhouse; G. D. Barton, Pembroke; and M. C. Hayward, Gonville and Caius.

Bachelor of Medicine.—C. de Lisle Carey, Emmanuel.

Bachelor of Surgery.—E. D. Telford, Gonville and Caius.

It is proposed to re-establish the professorship of surgery which has been suspended since the death of Sir George Humphry. The stipend is £600 a year. The professor will be eligible to a College fellowship and will be *ex-officio* surgeon to Addenbrooke's Hospital. He will be free to engage in private practice.

UNIVERSITY OF DURHAM.—At the Convocation held on April 25th the following degrees and diploma were conferred:—

Doctor in Medicine.—Reginald Alderson, M.B., B S. Durh.; Robert Hodgson Cole, M.B. Durh. (*in absentiâ*); Charles Edward Fenn, M.B. Durh.; Selina Fitzherbert Fox, M.B., B S. Durh., Lachlan George Fraser, M.B., B S. Durh.; John Tyrer Johnson, M.B., [illegible]

D[illegible] les [illegible] n, [illegible] as [illegible] an [illegible] .S. [illegible] ge
Wright Kemp Hector, L.R.C.P. & S. Edin., L.F.P.S. Glasg.; William Beeson Crawford Treasure, M.R.C.S. Eng., L.S.A.; and Herbert Leader [illegible]

Hankin, London School of Medicine for Women; Charles William Menelaus Hope, Hubert Wolstenholme Horan, Hugh Robert Kendal, Charles Robert Lease, and John Herbert McDowall, [illegible]

Tyne.

Bachelor in Surgery (B.S.).—Frederick George Armstrong, John Wilfrid Caton, Samuel Thomas Cochrane, and John Frederic [illegible]

B[illegible] es French, M.B., B S. [illegible] Durh., M.R.C.S. Eng., [illegible]

L.R.C.P. Garratt [illegible]

HEREFORDSHIRE GENERAL HOSPITAL.—For some years the Herefordshire General Hospital has been sadly in want of funds, and a large and energetic body of gentlemen have formed themselves into a committee with the idea of placing the institution on a sound financial basis. It is estimated that upwards of £4000 are required for the annual upkeep of the hospital and the revenue from all sources is about £3000 Towards the deficiency £400 have been already promised i[illegible] is now being made t[illegible] ity for the remaining [illegible] ass meeting was held in the Shirehall, Hereford, on April 25th, under the presidency of the Mayor (Mr. W. J. R. Symonds) and a resolution was unanimously adopted approving a proposal by which the workers of the county can supply the increased funds necessary to maintain the county hospital complete and effective in all its parts, and undertaking to use every effort to secure lasting and permanent success for the workers' monthly hospital penny scheme. Numerous lady collectors have been appointed and districts have been mapped out, and the proposal is for the ladies to call at each house monthly and to make a penny collection. If there is a response from only half the houses in the county the required amount will be forthcoming.

UNQUALIFIED PRACTICE; DEATH AND AN INQUEST.—An inquest was held on April 24th at the coroner's court, Kensington, on the body of Lieutenant-Colonel M. C. Garsia, C.B., commissioner of prisons, who died suddenly on April 20th. The evidence disclosed the following facts. On April 17th the deceased consulted a certain Mr. Dahkyl of 178, Holland-road, Kensington; the latter was a Greek who had studied medicine in Paris and described himself as "M.D., B.Sc., B.A. Paris, specialist for deafness, ear, nose, and throat diseases." Mr. Dahkyl provided the deceased with a number of different medicines for internal and external application, but it appeared that only the medicine described as the "compound resolutive syrup" had actually been taken by the deceased. Soon after taking this medicine Lieutenant-Colonel [illegible] unpleasant taste in his [illegible] day after commencing [illegible] r. Dahkyl complaining of his symptoms and saying that he believed that the medicine did not agree with him Shortly after writing this letter the deceased became much worse and Dr. Eric L. Pritchard was hurriedly called in, but a few minutes after his arrival the deceased became unconscious and soon afterwards expired. The post-mortem examination proved that the deceased's kidneys were in an early granular condition, that his heart was hypertrophied, and that the aorta and aortic valves were in a condition of atheromatous degeneration, while a large pulmonary infarct was apparently the cause of death. The coroner, Mr. C. Lux [illegible] from any blame in [illegible] of care or skill, d[illegible] present, which allows an unregistered practitioner to pursue his calling in this country without let or hindrance. As the case above recorded shows, a family was plunged into all the unpleasantness of a public inquest owing to the fact that the deceased had been treated by a practitioner who was not legally qualified in this country and who could not consequently provide a death certificate.

Royal College of Physicians of Ireland.—At a special meeting of the President and Fellows, held on April 24th, the following gentlemen were admitted to the Membership of the College: Dr. J. A. Matson, Dr. T. P. C. Kirkpatrick, and Dr. F. C. Purser.

In reference to an annotation in The Lancet of April 25th, p. 1181, in regard to "Dishes for Invalids in Hotels," our attention has been drawn by Messrs. Callard and Co. to the fact that they have for some years at their restaurant at 65, Regent-street, London, catered for invalids. "We make," they say, "a speciality of dishes which are free from starch and sugar, so enabling patients suffering from those diseases in which carbohydrates are contra-indicated to obtain suitable meals without fear of transgression."

Memorials to Medical Men.—For the purpose of providing a memorial to Dr. William Sanderson Wyman who died in Putney about 12 months ago a subscription was started by several local gentlemen. The appeal was readily responded to and a carved oak pulpit has been purchased and erected in St. John's Church, Putney-hill.—A marble bust of the late Dr. Patrick Miller of Exeter, with pedestal, has been presented to the Royal Devon and Exeter Hospital. Dr. Miller was elected honorary physician to the hospital in 1809, an office which he held for 50 years, resigning in 1860. He died in December, 1871.

The London Hospital.—On May 4th the Lord Mayor gave a dinner at the Mansion House for the purpose of furthering the interests of the London Hospital. In proposing the toast of the evening Sir Marcus Samuel said that 700 patients slept in the hospital every night and if the staff were included there were 1000 souls. The new out-patients' department had cost £70,000, and he was delighted to know that the King and the Queen had consented to open this wing. The new out-patients' department covered an area of 31,000 feet, a space which was formerly occupied by 38 houses producing a rental of £950, which the hospital had to lose to carry out the necessary work. A total of 162,000 patients were treated in a year. The annual expenditure of the hospital was £90,000, and its income was only £22,000. With regard to in-patients the number treated last year was 13,160. The hospital contained 40 wards, and a gift of £1000 would endow a bed and £500 a cot. Both Mr. Sydney Holland and he hoped to collect enough money for the purpose of endowing a ward to commemorate the forthcoming visit of the King and the Queen. During the course of the evening it was announced that the quinquennial appeal had up to the present resulted in a sum of £127,000.

Royal Institution.—The annual meeting of the members of the Royal Institution was held on May 1st, Sir James Crichton Browne, Treasurer and Vice-President, being in the chair. The annual report of the committee of visitors for the year 1902, testifying to the continued prosperity and efficient management of the institution, was read and adopted and the report on the Davy Faraday Research Laboratory of the Royal Institution which accompanied it was also read. Among the officers for the ensuing year may be mentioned:—President, the Duke of Northumberland; treasurer, Sir James Crichton Browne; secretary, Sir William Crookes; managers, Mr. Henry E. Armstrong, Sir Benjamin Baker, Mr. Shelford Bidwell, Sir Alexander Binnie, Sir Frederick Bramwell, Bart., Dr. Donald W. C. Hood, Lord Lister, Sir Felix Semon, Dr. J. Mackenzie Davidson, Mr. Francis Gaskell, and Dr. J. Dundas Grant. Before the conclusion of the proceedings Professor James Dewar said that experiments recently made in the laboratories of the institution revealed important exceptions to the generally accepted view as to the effect of low temperature in producing limitation or cessation of chemical action. It was well known that hydrogen and fluorine were the only two elementary gases which, on being brought into contact with each other, combined at ordinary temperatures in the dark without the aid of an external force such as electricity. Recent experiments showed that these two elements had a powerful mutual affinity, even at the lowest known temperatures, for when fluorine solidified by cooling was placed in contact with liquid hydrogen they combined with violence. A new field of inquiry, which might be called low-temperature chemistry, was thereby opened up.

Death of a Centenarian.—Mr. James Webber died at Barnstaple on April 21st in his 101st year.

Association for the Oral Instruction of the Deaf and Dumb.—The report of the committee of the training college for teachers and school children shows that steady progress has been made during the year 1902. Some of the earlier pupils who are now grown up are successfully fighting the battle of life, while the students trained at the association's training college for teachers are at work not only in all parts of the United Kingdom but in the colonies, both as teachers in schools and in private families, with excellent results. The work of the association is therefore not confined to the comparatively small number of deaf children who attend its practising school, but the teachers trained there confer the benefits of the pure oral system on many hundreds of children outside the sphere of the practising school in every English-speaking country. The practising school was attended during the past year by 47 pupils, 25 boys and 22 girls. The work of the association, however, is somewhat hampered by want of funds and it is to be hoped that there will be a generous response to the committee's appeal for assistance on the occasion of the festival dinner which is to take place on June 11th at the Hotel Cecil.

Presentations to Medical Practitioners.—Mr. William Blackwood, M.B., Ch.B. Edin., has been presented with a pipe and a tobacco jar by the members of the Camborne branch of the St. John Ambulance Association as a mark of appreciation for his services as honorary lecturer.—On April 29th Dr. and Mrs. Dysart McCaw were entertained at dinner in East Finchley, North London, and at a subsequent reception, which was numerously attended, Dr. McCaw was presented by his patients and friends (including his former medical neighbours) with a complimentary address, a purse of gold, and a solid silver tea and coffee service, with a tray on which the following inscription was engraved: "Presented to John Dysart McCaw, Esq., M.D., F.R.C.S., with a silver tea and coffee service, illuminated address, and purse of gold, by his patients and friends when leaving East Finchley, London, N., after fourteen years' residence, as a token of their high esteem and appreciation of his professional services and personal character. 29th April, 1903."—On May 4th the committee of the Tower Hamlets Dispensary, on behalf of the patients of the institution, presented Mr. Oscar E. Lemin, L.S.A. Lond., the retiring resident medical officer, with a framed illuminated address subscribed for by the patients of the institution.

National Hospital for the Paralysed and Epileptic.—The Lord Mayor presided over the festival dinner of the National Hospital for the Paralysed and Epileptic, held at the Hôtel Métropole, London, on April 30th. In speaking to the toast of "Success to the National Hospital for the Paralysed and Epileptic" the Lord Mayor said that fully qualified medical men of all nations resorted to the institution for instruction. An average of 500 medical men attended annually and the accumulated effect of the knowledge disseminated in this manner was enormous. He did not consider that it was fair to compare the cost of that hospital with others, because the care of the patients was one necessitating good diet and rest. Some hospitals discharged their patients before they ought to do so, some kept their patients on an average 18 days, some 28 days, and in comparing statistics of the number of patients passed through any hospital he was not sure that the greatest credit did not rest with those institutions that kept their patients the longest period of time. The Rev. Dr. H. Wace (chairman of the board of management) in responding to the toast referred to the harmonious working of all branches of the administration and drew particular attention to the great advantages derived from the association of the members of the medical staff with the board of management. Sir William Gowers in acknowledging the toast of "The Medical and Surgical Staff" proposed by Sir John A. Cockburn, M.D., said that it was remarkable how visitors from Germany, Holland, and the United States were astounded at the surgical results achieved at the hospital. The medical staff were indebted to the board of management for assistance in the investigation and scientific study of disease for the benefit of the patients. One result of the work was that acute ascending paralysis, which had hitherto baffled the study of pathologists all over the world, had within the last few weeks been discovered by their pathologist, Dr. E. Farquhar Buzzard, to be due to a special form of organism The Rev. Dr. Wace announced that the sum of £1882 had been subscribed towards meeting the year's deficit and raising the necessary money for the erection of new buildings.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, APRIL 30TH.

Calf Lymph.

MR. WEIR asked the President of the Local Government Board if he would state on wh [illegible] iph was supplied or sold by the Local [illegible] practitioners in private practice other [illegible] GRANT LAWSON, who replied, said · Th [illegible] ued by the Local Government Board is [illegible] to public vaccinators for use in vaccinations performed by them in that capacity and no charge is made for it.

The National Vaccine Establishment.

Mr. WEIR asked the President of the Local Government Board, seeing that under the Medical Department of the Local Government Board Vote there were two separate items for contingencies of £800 and £2000, the former item under sub head R, National Vaccine Establishment, and the latter under sub-head S would he state in more detail the nature of this expenditure.—Mr GRANT LAWSON, who replied, said: The two accounts referred to are intended to meet [illegible] iff at the vaccine establishments of [illegible] he cost of keeping additional calves [illegible] expenses which may be rendered [illegible] to prevail and there is in consequence an excessive demand for lymph. It is impracticable to state in detail what sums may be required on these accounts.

Health of Native Mine Labourers.

Mr. J. H. WHITLEY asked the Under Secretary of State for Foreign Affairs if he would take steps to have a record kept of the sickness and mortality which took place amongst the Central African natives during their indenture in the Transvaal mines.—Mr. CHAMBERLAIN answered. He said: I will ask Lord Milner to have such a record kept so far as it may be possible to do so.

Vital Statistics.

Mr. HENRY HOBHOUSE asked the President of the Local Government Board if, in view of the uselessness to county medical officers of health [illegible]

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Ahern, Richard, M.B., Ch.B. R.U.I., has been appointed Resident Medical Officer, Tooting Home Infirmary, Wandsworth and Clapham Union.

Allen, W. T. D., M.B., B.Ch., B.A.O. R.U.I., has been appointed Honorary Assistant Surgeon to St. George's Hospital for Diseases of the Skin, Liverpool.

Barclay, W. Bowie, L R.C.P., L.R.C.S. Edin., has been appointed Medical Officer at Aldershot.

Barrie, William Turnbull, M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory Act for the Hawick district of the county of Roxburgh.

Biddle, H. G., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Health for Broadstairs.

Blair, Alex., M.B., M.S. Glasg., has been appointed Medical Officer of Health to the Ashington Urban District Council.

Bond, Francis T., M.B. Lond., M.R.C.S., F.R.S. Edin., has been re-appointed Medical Officer of Health for the Chippenham Urban District.

Chamberlain, Katherine, M.B., B.S. Lond., has been appointed House Physician to the Royal Free Hospital.

Erhardt, Conrad Charles James, M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory Act for the Crosshills district of the county of Yorks.

Grattan, M. H., L.K.Q.C.P.I., has been appointed Certifying Surgeon under the Factory Act for the Ongar district of the county of Essex.

Grimwade, A. Sheppard, M.R.C.S., L.R.C.P., has been appointed Health Officer for the District of Caulfield, Victoria, Australia, and Assistant Anæsthetist to the Melbourne Hospital.

Gordon, A. Knyvett, M.B., B.C., B.A. Cantab., has been appointed Lecturer on Infectious Diseases at Owens College (Victoria University).

Jupe, F. I. M., L.S.A. Lond., has been appointed Certifying Surgeon under the Factory Act for the Histon district of the county of Cambridge.

Lower, N. Y., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory Act for the Presteign district of the county of Radnor.

Murray, W., M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory Act for the Hessle district of the county of York.

Sutter, R. R., M.D. Aberd., has been appointed Certifying Surgeon under the Factory Act for the Warboys district of the county of Hunts.

Whitehouse, A. Landon, M.R.C.S., L.R.C.P. Lond., L.D.S. Eng., has been appointed Dental Surgeon to the Westminster General Dispensary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Aberdeen Royal Infirmary.—Medical Superintendent. Salary £300 per annum, without residence.

Barra, Parish of.—Medical Officer and Public Vaccinator. Salary £119.

Birmingham Corporation.—Medical Officer of Health. Salary £1000 per annum.

Brecon and Radnor Asylum, Talgarth, R.S.O. Assistant Medical Officer, unmarried. Salary £140 per annum, with apartments, board, attendance, and laundry.

Cancer Hospital, Fulham, S.W.—House Surgeon for six months, renewable. Salary £70 per annum, with board and residence.

Cheshire County Asylum, Parkside, Macclesfield.—Junior Assistant Medical Officer, unmarried. Salary £140, rising to £160 per annum, with board, apartments, washing, and attendance.

East Suffolk and Ipswich Hospital.—Second House Surgeon, single. Salary £80 per annum, with board, lodging, and washing.

Evelina Hospital for Sick Children, Southwark Bridge-road, S.E.—Anæsthetist. Honorarium £25 per annum.

Hastings, St. Leonards, and East Sussex Hospital.—House Surgeon, unmarried. Salary £75 per annum, with residence, board, and washing.

Hulme Dispensary, Dale-street, Stretford-road, Manchester.—House Surgeon. Salary £150 per annum, with apartments, attendance, coal, and gas.

Liverpool Eye and Ear Infirmary.—House Surgeon. Salary £80, with residence and maintenance.

London County Council Epileptic Colony, Ewell, Surrey.—Assistant Medical Officer. Salary £200 per annum, with board, furnished apartments, and washing.

London Hospital, Whitechapel, E.—Assistant Obstetric Physician.

Manchester Royal Infirmary.—Resident Surgical Officer, unmarried. Salary £150 per annum, with board and residence.

Manchester Southern and Maternity Hospital—Resident House Surgeon. Salary £100 per annum and board.

Metropolitan Hospital, Kingsland-road, N.E.—Dental Surgeon.

Middlesex Hospital, W.—Director of Cancer Research Laboratories. Salary £500, rising to £800 per annum. Also Research Scholarship, value £105 per annum.

National Dental Hospital and College.—Anæsthetist on Tuesdays.

Newcastle-upon-Tyne Dispensary.—Visiting Medical Assistant. Salary £160, for first year and £180 afterwards.

Newport and Monmouthshire Hospital.—Assistant House Surgeon. Salary £50 per annum, with board, residence, and washing.

North Devon Infirmary, Barnstaple, Devon.—House Surgeon. Salary £80 per annum, with board, residence, and washing.

North-Eastern Hospital for Children, Hackney-road, Bethnal-Green, E.—House Physician, House Surgeon, and Resident Casualty Officer for six months. Salary in each case at rate of £80 per annum, with board, residence, and washing.

North-West London Hospital, Kentish Town-road.—Resident Medical Officer, also Assistant Resident Medical Officer, for six months. Salary at rate of £50 per annum in each case, with board, residence, and washing.

Royal College of Surgeons of England.—Hunterian Professors, Erasmus Wilson Lecturer, and Arris and Gale Lecturer for the ensuing year.

Royal Southern Hospital, Liverpool.—Junior House Surgeon. Salary 60 guineas per annum.

Royal Westminster Ophthalmic Hospital, King William-street, West Strand, W.C.—House Surgeon for six months. Honorarium £25. Also Clinical Assistants for six months.

St. Mary's Hospital, Quay-street, Manchester.—Medical Officer for six months, renewable. Salary £65 per annum, with board and residence.

Sheffield Royal Hospital.—Junior Assistant House Surgeon, unmarried. Salary £50 per annum, with board, washing, and apartments.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Burton, Westmorland; Tamworth, Stafford; Dunfanaghy, Donegal; Strathdon, Aberdeen; Wootton Bassett, Wilts; Haslingden, Lancaster; and at Stanford-le-Hope, Essex.

Births, Marriages, and Deaths.

BIRTHS.

Corbin.—On May 2nd, at Beckenham, Kent, the wife of E. R. St. Clair Corbin, M.B. Lond., M.R.C.S., of a son.

Croft.—On April 30th, at Fenton, Staffs., the wife of J. T. H. Croft, M.R.C.S., L.R.C.P. Lond., of a daughter.

MARRIAGES.

Hubert—Williams.—On Tuesday, April 21st, at St. Martin's Church, [illegible] G. H. Torrance, assisted by the Rev. E. A. [illegible] e parish, William Arthur Hubert, M.R.C.S. [illegible] Sussex, to Gertrude Louisa, only daughter [illegible] of Rose Hill, Dorking.

Storrs—Simon.—On April 30th, at St. Peter's, Eaton-square, William Townsend Storrs, M.R.C.S., L.R.C.P. Lond., to Maude Blanche, only daughter of Mr. and Mrs. Alfred Simon.

DEATHS.

Bullock.—On April 30th, at Eastgate, Warwick, Thomas William Bullock, M.R.C.S., L.S.A., aged 65 years.

Gray.—On April 27th, at Adelaide-place, Newcastle, Co. Down, George Gray, M.D. R.U.I., J.P.

Noble.—On May 4th, at 29, Wellington-square, Oxford, Eric Raymond Noble, Balliol College, Oxford, younger son of Samuel Clarke Noble, M.R.C.S., L.S.A., of Kendal, aged 23.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

POST MORTEM EXAMINATIONS APART FROM A CORONER'S INQUEST.

AT a recent meeting of the Ealing town council a question was raised which included some important points. The facts were as follows:—A working man in the council's employ died in the Ealing cottage hospital. The cause of death having been duly certified the body was removed to the home of the deceased, a cottage, there to await burial. On the following day some of the medical staff of the hospital, including the practitioner who had attended the deceased, called at the house and asked the permission of the widow to make a post mortem examination. This consent being obtained an examination was made, but only of a very slight character, for the body was not taken out of the coffin. At the meeting of the council Mr. Councillor George Taylor asked the council as the sanitary authority, whether in future it would take care that when post mortem examinations were made upon bodies of patients dying in the hospital such examinations should be made in the hospital mortuary. Mr. Councillor Taylor contended [illegible] rs to make a post mortem examinatio[illegible] yor, however, said that it was a mat[illegible] the council's cognisance and the clerk said that the *council had no* power to prevent post mortem examinations being made in a private house. The case in question is unimportant in itself and there would, we suppose, have been no difficulty in the post mortem examination having been made in the hospital post mortem room as *the patient had died in the hospital.* There was no question at any time of an inquest and the post mortem examination was asked for simply for the sake of confirmatory information. Such cases often happen, but the point arises, has any ratepayer a right to the use of the parish mortuary? Suppose a person dies in a private house. The medical man *in attendance, although cognisant* of the cause of death, wishes some further information and asks the surviving relatives if they object to a post mortem examination being held. They say that they have no objection, only that they do not wish the examination to be performed in the house. Has the medical man as a ratepayer or have the relatives as representatives of a deceased ratepayer the right to the public mortuary? If so, whose duty is it to remove the body from the house to the mortuary—the undertaker employed by the family of the deceased or the parish authorities? Can the public mortuary be used by any ratepayer without a fee, and if not what fee should be charged?

In endeavouring to answer these questions it must be remembered that post mortem examinations are not held in mortuaries, which are places for the reception of dead bodies before interment. Local authorities may provide and maintain places (which must not be at a workhouse or mortuary) for the reception of dead bodies during the time required to conduct any post mortem examination ordered by a coroner or other constituted authority, and in London the County Council can require the provision of such places. The private use of such places, either as a matter of right or otherwise does not seem to be contemplated by the Acts giving power to provide them, and it is therefore doubtful whether the authorities which have the duty of making regulations for their management could properly permit any such use to be made of them. It is, however, conceivable that such use might be permitted in special circumstances if application were made.

A REPUDIATION.

To the Editors of THE LANCET.

SIRS,—I have been informed that a slip was distributed last week at [illegible] ate from [illegible] owledge [illegible]

Harley-street, W., May 4th, 1903. R. LAKE.

To the Editors of THE LANCET.

SIRS,—In justice to Mr. Richard Lake of 19, Harley-street, I wish to state that it was not with his knowledge or consent that I published a copy of the certificate which he issued as to Miss Ada Reeve's indisposition last week. I am, Sirs, yours faithfully,

Lyric Theatre, May 5th, 1903. TOM B. DAVIS.

ANOTHER REPUDIATION.

To the Editors of THE LANCET.

SIRS,—I have just received a surgical catalogue from Messrs. Salt and Sons of this town and in it I find my name printed in large letters in connexion with an instrument. My name has been inserted without my knowledge and I have requested Messrs. Salt to suppress it.

I am, Sirs, yours faithfully,
C. W. SUCKLING, M.D. Lond.,
Consulting Physician to the Queen's Hospital.
Birmingham, April 30th, 1903.

THE DIAGNOSIS OF SMALL-POX.

To the Editors of THE LANCET.

SIRS,—Many years ago, when I had more opportunities of seeing small-pox patients, I observed that discrete and atypical cases presented an arrangement of the vesicles which although not mentioned in the ordinary text books, may possess some diagnostic value. In any given case it may be noticed that several of the vesicles are disposed in pairs, a large vesicle with a smaller one immediately adjacent, also, [illegible] e seen three vesicles, [illegible] placed close to each [illegible] ing a part of but being distinct from the general eruption. In the few cases of discrete small-pox that I have seen since I found this arrangement of some of the vesicles, so that it appears to be sufficiently constant in mild cases of variola to be of some value in assisting diagnosis.

I am, Sirs, yours faithfully,
May 4th, 1903. S. BINGHAM.

GOVERNMENT ETYMOLOGY.

IN a recent notice of a handy form of stationery called "Letterettes" while we praised the invention we felt bound to comment unfavourably upon its name. Messrs. John Walker and Co., Limited, the proprietors of Letterettes, have since written: "We sympathise with you in your objection to the name. But although we are 'proprietors of manufactured goods' we are also publishers of one or two not unimportant educational books, and we can assure you that our 'respect for etymology' is by no means as scant as you appear to imagine. We have it, however, on the authority of the Government that 'Letterette' is '*an English word in common use,*' so that you will see that if we have sinned we are by no means alone in this respect. We must confess that we could find no other word that so exactly described the article in such an easy manner." It appears that Messrs. John Walker and Co. applied to Government to register their invention under the name of Letterettes and were then told that this could not be done because the word Letterette was an English one in common use.

THE NOTTINGHAM CHILDREN'S HOSPITAL.

IN THE LANCET *of March 7th (p. 699) we published an article on the* dispute which has arisen at the Nottingham Children's Hospital. In that article the action of the lady superintendent was adversely commented on. She was charged *inter alia* with failing to report the case of a sick nurse to the house surgeon and with dismissing a *locum tenent lady dispenser. Having heard the statement of the* lady superintendent on this matter we are satisfied that we unintentionally did her an injustice and that she acted in accordance with the rules of the hospital.

MOTOR CARS FOR MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—Messrs. Hewetsons have asked me to give results of my experience with their four and a half horse-power Benz which I bought early in June, 1902. This I am pleased to do, as perhaps I was a little too severe in the letters which I sent to THE LANCET in 1900 and 1902 concerning my worries with their three horse-power car. I purchased my present one as already stated, in June, 1902, and received it with metal wheels which Messrs. Hewetsons very kindly lent me until September when I received the artillery wheels which I had ordered. I had the car fitted at Hewetsons' coach builders with a hood, glass extension and side flaps, so that in wet weather I was absolutely covered and protected. I have used the car constantly since I have had it for about five hours a day. In addition during term my daughter has gone in it to school at Blackheath, a distance of some two and a half miles. I have also had three holidays in the car, one through Oxford, Cheltenham, Worcester, Hereford, Abergavenny, Cardiff, Chepstow, and Gloucester, and (with my wife and child) over Birdlip, through Winchester, Swindon, Marlborough, Salisbury, and *viâ* Winchester and Guildford home. The only casualties were that last year a bolt drew through the frame and so caused the chain to be thrown, and about a month ago the rear axle broke. In both instances, though in the latter case the period of guarantee had passed, Messrs. Hewetsons replaced the parts free of charge. The only other trouble was that the spindle inlet valve broke which cost 12*s.* 6*d.* to replace, and that the spindle of the friction wheel that drives the pump had to be bushed and new leathers fitted and I expect shortly to have to get new tyres on the driving wheels and perhaps new chains. In conclusion, I can only say that I am very pleased with my car and with the way in which it has behaved.

I am, Sirs, yours faithfully,
CHARLES T. W. HIRSCH, M.R.C.S. Eng.,
L.R.C.P. Lond., L.S.A.,
Public Vaccinator and Police Surgeon, Woolwich; late
Medical Officer for Rewa, Colonial Medical
Woolwich, April 20th, 1903. Service, Fiji.

"GELINEAU DRAGES."

To the Editors of THE LANCET.

SIRS,—Could any of your readers give me their experiences of "Gelineau drages" in epilepsy. Information will oblige.

Yours faithfully,
Putney, S.W., April 29th, 1903. J. [illegible]

A POINT OF ETIQUETTE.

To the Editors of THE LANCET.

SIRS,—The following is a case on which I would like to have your opinion. A certain Mrs. O has been long in the habit of visiting an aged aunt. On Saturday she noticed a change in her condition and she asked the nearest medical man, Dr. X, to see her. He was ill in bed and the messenger was informed to get someone else. Mrs. O asks her own medical adviser, Dr. Y, to see her and he promises to call next day, as he lives six and a half miles distant. Meantime the old lady is apparently worse and another practitioner, Dr. Z, is called in. He lives in the same village as Dr. X and he went immediately and prescribed. Next Sunday morning Dr. Y calls, also Dr. Z, but at different times. However, Dr. Y assures Mrs. O that the case is safe in Dr. Z's hands and he will look after the patient. On Monday morning Dr. X turns up and he asks Mrs. O to tell Dr. Z not to come back as the patient is his. It is a good many years since Dr. X was in the house. Mrs. O, in her anxiety to preserve peace, asks Dr. Z not to come back and he quietly and without demur consents to do so. Dr. Y has not again had an opportunity of calling, though it is the strong desire of the family that he should do so.

I will feel very much obliged if you will express your views on this case, the conduct of Dr. X towards his brother practitioner being totally incomprehensible to, Yours faithfully,

May 1st, 1903. NE PLUS ULTRA.

⁂ *As Dr. X was summoned in an emergency and was unable to* attend the case when so summoned it does not appear to us that he has much *locus standi.* At any rate, the patient or the patient's friends can decide, in the circumstances detailed, which medical man should remain in attendance upon the case.—ED. L.

UNSEEMLY ADVERTISEMENT.

To the Editors of THE LANCET.

SIRS,—I was passing through Dunmanway some days ago and saw the following advertisement on the front of a house:—

MEDICAL HALL.

PURE DRUGS AND CHEMICALS.

PRESCRIPTIONS ACCURATELY COMPOUNDED.

HORSE AND CATTLE MEDICINE.

—— —— M.D., Surgeon.

The advertisement appeared in *very* large letters.

I am, Sirs, yours faithfully,

May 4th, 1903. NEMO.

UNPRECEDENTED.

To the Editors of THE LANCET.

SIRS,—May I record a remarkable event that has recently occurred in my practice? A child near my house playing in the street fell upon some broken glass and cut herself. The usual crowd of strangers accompanied the patient to a doctor (i.e., to me) and I dressed the wound. Then one of the strangers *volunteered to pay me a fee—and did so!* I have been in practice for 15 years but such an event has never happened to me before. I feel that I ought to publish it.

I am, Sirs, yours faithfully,

May 4th, 1903. E. A. L.

ANTIKAMNIA.

To the Editors of THE LANCET.

SIRS,—In the advertisement pages of THE LANCET of May 2nd is one from the Antikamnia Chemical Company. They say that this drug "positively will not depress the heart." I have very grave doubts on this point and in fact in two cases, one being myself, I will assert that it did positively depress the heart. My own experience is as follows. I had been suffering from toothache and had taken three five-grain doses of antikamnia with the interval of 20 minutes between each dose. At the end of that time not feeling much better I had risen from a sofa to seek further aid when I was overtaken with giddiness and fell back in a fainting condition, my face covered with sweat and the pulse feeble and irregular. I recovered after a dose of brandy-and-soda. The second patient was a young lady to whom I had given two five-grain tabloids together for the lumbar pain of influenza. I was sent for about 20 minutes later and found her with an irregular pulse and heart sounds almost inaudible. She improved after an injection of ether and hot bottles to her feet.—I am, Sirs, yours faithfully,

E. H. WORTH, M.R.C.S. Eng.

Mitcham-lane, Streatham, S.W., May 2nd, 1903.

◆

K. D.—(*a*) The employment of unqualified assistants is prohibited by the General *Medical Council and technically the gentleman* mentioned is unqualified. The possession of a foreign medical degree might be held by the General Medical Council to save his principal from the accusation of "covering" but our correspondent is advised not to run the risk. (*b*) We are not prepared to guess what view the General Medical Council might take of the conduct of a medical man who employed a dispenser to canvass for votes for an appointment. We doubt if a professional offence can be proved whatever may be thought of the taste of the proceeding. The General Medical Council has declared its disapproval of medical aid societies where canvassing is employed because the medical officers of such societies are placed in the position of advertising themselves to the lay public; but this is a totally different position.

Scot.—The regulations which govern practice in America by holders of British qualifications vary in each particular state or territory. In some states examinations are held, while in others indorsement by the Board of Health is sufficient. The fees vary from $10 to $25. If our correspondent will tell us the state or territory in which he wishes to practise we will endeavour to help him further.

X. Y. Z.—(*a*) We know of no text-book on the subject. (*b*) In the absence of any precedent in the matter we consider that a candidate's papers in an examination, after they have been looked over by the examiners, belong to the body appointing the examination. Possibly a lawyer might see another side to what is a purely legal question.

Practice in Canada.—As a rule, medical men holding British diplomas and degrees can practise in Canada on obtaining a licence from the Provincial Medical Boards. They must, however, be registered and the fees vary from £2 to £20, according to the province selected.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect, and do so collect from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates whatever be the weight of any of the copies so supplied Address—THE MANAGER THE LANCET OFFICES, 423, STRAND LONDON, ENGLAND

A Clinical Lecture

ON

COMBINED CONGENITAL DEFECTS AND ORGANIC DISEASE OF THE HEART.

Delivered in the Royal Infirmary, Newcastle-upon-Tyne,

BY THOMAS OLIVER, LL.D., M.D. GLASG., F.R.C.P. LOND.,

PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

GENTLEMEN,—In Quain's Anatomy, 1892, vol. ii., part 2, p. 386, Professor G. D. Thane, after alluding to the fact that the natural aortic arch of man and of all mammalia is a left one, produced by the persistence and development of the left fourth arch, says: "Reference may here be made to the complete lateral transposition which is occasionally seen in the aortic arch and pulmonary arteries as well as in the great veins and several divisions of the heart and which may affect only those parts (dextrocardia) or may be accompanied by a similar transposition of the viscera of the body generally (situs inversus). Such cases are usually unattended by any disturbance of function or other unnatural conditions of structure. There is, in fact, only a change of position which may be compared to that in which the natural parts would appear if viewed by reflection from a mirror. From the direction of the apex beat towards the right and other *deviations from the normal position the existence of this* transposition is capable of being ascertained during life."

In December, 1898, the subject of the following notes first came under my care. He was then a youth aged 18 years, slightly under the average in height, but was otherwise well developed, healthy-looking, and rather florid. Until three years previously he had been a healthy lad and had taken his part in the ordinary games of boyhood without inconvenience or fatigue. At this period he had rheumatic fever which confined him to bed for three weeks. He made a good recovery but had never felt so well since He had been conscious of shortness of breath at times and had suffered from palpitation. The pulse was 80, water-hammer in character, and collapsed readily under the finger. The apex of the heart was seen and felt beating between the fifth and sixth ribs on the right side of the body fully one inch below the right nipple. Here the impulse was well marked and was equal in force to that felt in ordinary circumstances in the usual apex are [illegible] dilated. [illegible] Over the [illegible] generally [illegible] murmurs. These murmurs were carried downwards and to the right for about two inches, as well as a short distance down the [illegible] apex area [illegible] nounced [illegible] and healthy all over There was no sign of pleural effusion *or of pneumothorax*, nor a history of previous lung trouble that was capable of explaining the cardiac displacement. Both sides of the chest were symmetrical and measured equally 15½ inches. Below the sixth rib on the right side there was a comparatively limited area of dulness, while on the left side dulness began at a similar level and was carried downwards to the lower border of the left costal arch and round to the back. From the size of this area of dulness on the left side it was suggestive of a transposed liver. Between these two areas of dulness was one that gave a tympanitic note when percussed. The abdomen was otherwise normal. The urine contained urates but was free from albumin and sugar. He was ordered a mixture of digitalis, ammonia, and spirit of chloroform, and pills of mercury with colocynth occasionally. When I saw him three weeks afterwards he had wonderfully improved so far as his symptoms were concerned, and on Feb. 20th, 1899, the patient was still keeping well. The pulse was 80 and water-hammer in character. *On June 12th, 1899*, the pulse was 82 and of a water-hammer type. There were systolic and diastolic murmurs over the base of the heart. The diastolic murmur, while ceasing at the third left costal cartilage, was carried down to the cardiac impulse just internal to the right nipple. There was no murmur heard over the back of the chest at the inferior angle of either scapula.

At varying intervals of from four to six months I have had the opportunity of examining this youth and of recording facts. It is sufficient to say that there have been a gradual increase in the size of the heart and a development of a systolic murmur over the apex area, suggesting hypertrophy of the left ventricle and mitral regurgitation. In the autumn of 1900 the cardiac impulse was seen and felt two inches below the right nipple and in a line with it, but beyond the first sound at the apex having been replaced by a murmur the cardiac bruits remain the same. With the development of the mitral murmur the heart symptoms became less urgent. By July, 1901, he had so improved in health and lost his *cardiac symptoms that he was indulging in cycling and mild* tennis-playing. His pulse was 84 and of a water-hammer type. There were systolic and diastolic murmurs at the base of the heart conducted down the sternum while at the apex area there was a well-marked systolic murmur. There was very slight epigastric pulsation. When re-examined in April, 1902, the condition of the heart was unaltered, his general state of health was good, and he was remaining free from cardiac symptoms My diagnosis is aortic and mitral regurgitation occurring in a displaced heart (dextrocardia) [illegible] to be very [illegible] Practice of [illegible] congenital [illegible] direction of the heart is changed so that the apex points to the right instead of the left, sometimes the position is vertical. These displacements are frequently found associated with general transposition of the viscera. In this general transposition the heart lies upon the right side (dextrocardia). The fundus of the stomach lies upon the right side with the spleen, while the pylorus and duodenum lie upon the left. The rest of the intestine is likewise changed. The cæcum lies upon the left, the sigmoid flexure and rectum lie upon the right. The ascending and descending colon change names. The liver lies in the left hypochondrium and the right and left lobes change places. The gall-bladder, the gall-ducts, the ligaments and fissures show corresponding dislocation. The right kidney lies higher than the left and the [illegible] the right. *Malformations of* [illegible] in typical situs inversus. ... [illegible] viscera is explained by an abnormal habitus with reference to the umbilical vesicle in the embryo. Dareste showed that when a hen's egg is warmed on one side a transposition of the viscera more or less pronounced occurs in the majority of cases. The inversion takes place whenever the embryo does not turn at the right time from the right to the left. The condition is not now so rare as was formerly believed, since the advance of methods of examination discloses the transposition during life. Hitherto the alteration was discovered only upon the post-mortem table. ..... The total transposition of the viscera in no way interferes with long life and perfect action of all the organs. Symptoms, when present, are due to complications or accidental associated malformations."

The diagnosis of inversion of the heart is easy enough, since it is sufficient to feel the apex beating in the right instead of in the left side of the chest. Percussion confirms the situation of the organ. In every case it must be demonstrated that the heart has not been displaced to the right by pleuritic effusion occupying the left chest; also that there has not been disease of the right lung followed by adhesion and retraction Constantin Paul had the opportunity of observing two cases at the St. Antoine Hospital and to these I will briefly allude. Case 1.—The patient was a woman, aged 35 years, who showed an arrest of development on the left side of the body. In her the apex beat of the heart was felt in the fifth right intercostal space 10 centimetres (four inches) from the middle line of the sternum. The heart showed slight left-sided hypertrophy. There was neither souffle nor irregularity of rhythm. The liver was not displaced. There was atrophy of the left chest and the left breast was smaller than the right, a remark that also applied to the left forearm Case 2.—The patient was a lad, aged 15 years, *incompletely* developed, whose heart was beating in the right side of the chest in the fifth intercostal space seven centimetres (two and three-quarter inches) from the mid-line. On auscultation the heart was normal. The liver on the left side of the body was of normal size. The spleen on the right side seemed to be small. The patient was mainly left-handed. Constantin Paul saw this patient 16 years afterwards; he had grown very little. The heart had developed to some extent; its apex beat was further removed to the right, being eight and a half centimetres (three and a half inches) from the middle line of the sternum.

From these cases it will at once be seen that inversion of the heart may or may not be accompanied by inversion of the other viscera. In Paul's second case the inversion appears to have been pretty complete, since it involved other organs. Inversion of the viscera does not necessarily produce any serious trouble, for persons who are the subjects of it may be ignorant of the fact. Still, it is only proper that the transposition should not pass unperceived by the medical attendant. There are some congenital defects of the heart that are incompatible with life—e.g., where there is ectopia cordis—i.e., where the heart lies outside the body—a defect that belongs rather to teratology than to medicine.

Professor A. Birmingham published in the *Journal of Anatomy and Physiology*, vol. xxvii., 1893, p. 139, the details of a case of dextrocardia with congenital abnormalities in a young woman, aged 20 years, who was of rather short stature and who during life had been very cyanosed. In listening to her chest Dr. Joseph F. O'Carroll, the medical attendant, heard a loud harsh systolic murmur from the second right intercostal space downwards to below the right nipple and into the right axilla. On opening the chest after death not only was the apex of the heart found to be directed to the right but the whole organ was twisted on its long axis, the aorta was seen to rise from the right ventricle in the situation of the pulmonary artery, while the pulmonary artery arose from the same ventricle, its orifice being placed midway between the base and apex among the columnæ carneæ; its lumen was only a quarter of an inch. The inter-ventricular septum was perforated so that the freest communication possible existed between the two cavities. The inter-auricular septum was also incomplete.

In the *Journal of Anatomy and Physiology*, vol. xxvi., 1892, p 117, Professor T. Wardrop Griffith describes the anatomical peculiarities observed in a child six months old, in whom there were detected during life dextrocardia with very marked cyanosis and transposition of the viscera and in whom after death the two auricles were found communicating with a ventricle that was divided by an incomplete septum; the inferior vena cava was absent, its place being taken by a vessel formed by the junction of four hepatic veins.

I have abstracted these cases from medical literature in order to emphasise the remark that there may be in dextrocardia some congenital defect in addition to right-sided displacement of the heart. In all circumstances, as already mentioned, it is necessary to eliminate, where the heart is found beating in the right chest, such causes as left-sided pleural effusion, right-sided pulmonary excavation with retraction of lung and pericardial adhesion, also left-sided pneumo-thorax. In my case of dextrocardia recorded above there is no evidence of there having been any chest affection capable of causing displacement of the heart; besides, a skiagram that was taken shows, both from the shape of the organ and from the direction of the apex, that the dextrocardia is congenital The other point—one that is more difficult to answer—is whether the displaced heart was congenitally perfect and free from disease and has simply become affected as a consequence of rheumatic fever through an endocardial lesion leading to aortic regurgitation, or whether the systolic and diastolic murmurs that are heard indicate defective septa and abnormality of the valves. In favour of the view that there is aortic regurgitation and that it is the consequence of endocarditis we have (1) the previous good health of the patient until a particular illness; (2) the history of rheumatic fever, an illness which experience shows is one of the most frequent causes of incompetent aortic valves, especially in young subjects; (3) the absence of cyanosis at birth and all through life—although cyanosis, I admit, is not necessarily present when there are defective septa; (4) the water-hammer character of the pulse and its typical aortic type, as shown in some sphygmograms that were taken; (5) exaggeration of the cardiac murmurs and the development under observation of a mitral regurgitant murmur; (6) the fact that there are no loud harsh murmurs heard all over the chest as occurs in most cases of congenital heart defect; and (7) that although *diastolic* murmurs may be heard in congenital heart disease yet they are extremely rare. I have given my reasons for not regarding the case as one of defective septa nor do I think that there is a patent ductus arteriosus. In such a condition a thrill is felt over the second left intercostal cartilage and a very prolonged systolic murmur is heard, rather a late or post-systolic murmur in fact, followed by an accentuated second sound at the base of the heart, and attended by well-marked dyspnœa on exertion and by cyanosis.

With the second case, that of a man who died recently, many of you are familiar, having seen the patient with me in the wards upstairs. He was a ship's carpenter, aged 37 years, and was admitted under my care on April 1st, 1902, complaining of shortness of breath, cough, and swelling of the legs of two years' duration. Beyond the fact of his mother having died from apoplexy there was nothing in the family history that calls for comment. The patient had indulged freely in alcohol. There was no history of syphilis or of rheumatic fever. About six years before, when working in a shipyard on the Clyde, he fell a distance of 25 feet and injured the front of his chest. He was taken to the Western Infirmary, Glasgow, where he lay for about two months under the care of Professor (now Sir) William T. Gairdner. No ribs were broken as a consequence of the accident nor was there any spitting of blood. Until two years previously, except for the accident alluded to, he was a healthy man. At this date he began to suffer from shortness of breath and swelling of the feet. He also had cough and morning sickness and was consequently unable to follow his employment. Owing to difficulty of breathing the patient had had of late to be propped up in bed. His face was pale, his cheeks were slightly bluish, and his lips were cyanosed. The pulse was 66, feeble and irregular; the legs were œdematous. There was also œdema of the arms and hands; the hands were cold and cyanosed. There was venous pulsation in the neck. The urine was high-coloured, scanty, with a specific gravity of 1025, and contained a trace of albumin. The chest was barrel-shaped with wide intercostal angle and its wall was slightly œdematous. The heart's impulse was diffuse and wavy. Epigastric pulsation was well marked; pulsation was also observed in the third, fourth, and fifth interspaces to the left of the sternum. The apex beat was felt in the sixth interspace two inches external to the left nipple. A well-marked and prolonged thrill could be felt there which was entirely systolic; it was long and quivering. The area of cardiac dulness was increased transversely. At the apex there was heard a loud murmur occupying the whole of the systole, too coarse and rough to be called musical, rather sharp in its incidence, yet never preceding the systole, and while well conducted towards the left axilla it was also very distinct internal to the apex beat. This loud systolic murmur was heard over the whole of the left chest posteriorly and all down the spine as far as the sacrum. At times the second sound was reduplicated at the apex. Over the aortic area there was a systolic murmur which was conducted into the vessels of the neck. A well-marked systolic murmur was heard over the tricuspid area and as the left base of the heart was approached from this area there could be heard a diastolic murmur which at times was not very audible owing to the second sound being distinctly accentuated. It was difficult to assign to this diastolic murmur an origin that was satisfactory. It did not seem to come quite within the category of an aortic murmur nor was it apparently one of those diastolic murmurs that are occasionally met with in mitral stenosis. Its source, therefore, must be left an open question. In the lungs numerous bronchial râles were heard and there was dulness over the base of each lung. The abdomen was distended, being resonant in front and dull in the flanks; fluctuation was readily obtained. The liver was enlarged and tender. Splenic dulness was not perceptibly increased.

Under treatment the patient temporarily improved. The cardiac murmurs, however, remained unaltered and beyond the fact that later there was a disappearance of the second sound at the apex there was no new development that calls for notice during the four weeks that he was under my care. On the last day of April, at a time when the dropsy of the extremities was disappearing, the patient unfortunately grazed his leg on the bedstead. A day or two after this the skin of the leg became red and acutely inflamed like erysipelas. He had a rigor and the temperature rose to 101·4° F. A few days prior to the accident his general condition was, on the whole, satisfactory. The patient, as already stated, seemed to be improving. Under the administration of digitalis, to which subsequently diuretin was added, the quantity of urine rose from 22 ounces on April 22nd to 136 ounces on May 1st and concurrently with this the dropsy was fast disappearing. In addition to the rapid diminution of the œdema the albumin disappeared from the urine, a circumstance that suggested a cardiac origin for the albuminuria. It was at this stage that the second cardiac sound ceased to be audible at the apex and that notwithstanding the large quantities of urine passed the breath sounds were still very deficient over the base of each lung. The patient died suddenly on the evening of May 2nd. Dr. James Muirhead had been speaking to him and had just left him when his head was observed to fall back and he was found to be dead.

At the post-mortem examination both pleural cavities were found to contain a large quantity of serum. The lungs were congested and œdematous. The heart was enlarged. The left ventricle was hypertrophied but the enlargement affected particularly the right side of the heart. The aortic valve was competent; that of the pulmonary artery was incompetent. On opening the left ventricle its wall was observed to be of more than usual thickness and its cavity was slightly dilated. The mitral orifice was incompetent. The valves were thickened at the tips, along their margins, and at the bases; the *chordæ tendineæ* were thickened. The aorta was small, being about half the size of the pulmonary artery. Its valve was composed of only two segments. The interior of the aorta was healthy and the coronary arteries were normal. Stretching across the interior of the left ventricle just underneath the aortic orifice was a misplaced chorda tendinea. The pulmonary artery was widely dilated; its valve segments were normal in number but they were thickened along their free border; so, too, were the corpora *Arantii.* The valve was incompetent and the thickening of its segments was such as would also probably cause slight obstruction to the circulation. The right ventricle was large and dilated. There was a large patent foramen ovale in the inter-auricular septum which was imperfectly closed by a flap. The liver was enlarged and nutmeg-like. The spleen presented nothing abnormal. The kidneys were congested (heart kidneys) and firm, their capsule stripping off readily.

As the patient had been under the care of Professor Gairdner in the Western Infirmary, Glasgow, a few years previously I wrote to Sir William Gairdner and asked him if he could remember the patient or throw any light upon the case. I have received through Dr. R. Barclay Ness, one of the assistant physicians to that institution, the clinical notes bearing upon the case. I have Sir William Gairdner's permission to reproduce these. The notes exhibit, as might be expected, the usual carefulness and completeness which old Glasgow students remember as characteristic of the methods of their esteemed teacher. When I came to compare the two sets of notes there were a few discrepancies as regards dates and origin of the illness that are naturally to be expected from a patient whose illness has lasted a few years and these can at once be set aside although some of them may be incidentally mentioned so as to bring the details of Sir William Gairdner's clinical examination into line with my own.

A man, aged 32, shipwright, admitted into the Western Infirmary Oct. 28th, 1897, complaining of breathlessness and swelling of feet. Note by Professor Gairdner, Oct. 29th, 1897.—Admitted with a very evident cardiac lesion. Apex [illegible]
three-quarters of an inch o [illegible]

certainly might be capable of escaping observation and might be [illegible]

Sir William Gairdner's notes were taken four and a half years ago and allowing for such pathological changes as are bound to occur in a diseased heart during this period there is, on the whole, pretty general agreement between the clinical data then and recently. Sir William Gairdner, like myself, regarded the loud systolic murmur as pointing to mitral regurgitation. He, too, was struck by its wide propagation and also by the fact that there was a basic diastolic murmur which was not localised and was extremely apt to escape detection. The heart had during these four and a half years undergone some change: it had become still further enlarged, its apex beat was more displaced to the left than previously and in the meantime there had developed a tricuspid murmur. At the necropsy the heart presented combined congenital defects and organic lesions—e.g., (1) a patent foramen ovale and aortic bicuspid valve, and (2) a mitral regurgitation and thickened valve segments, also widely dilated pulmonary artery with thickened valves which closed imperfectly.

With a heart showing such a number of lesions as that of the patient in the above case it is difficult to say definitely to which of them the loud prolonged systolic murmur is to be attributed. Bruits in the cardio-vascular system are mainly due to vibration, owing to currents of blood being forced with rapidity through a constricted orifice into a wider channel beyond and causing shock, or it may be that the impact of this moving liquid throws the more tranquil mass into a series of eddies. I am therefore disposed to think that in consequence of the hypertrophied wall of the left ventricle, the thickened mitral curtains, and the narrow aorta, rendered narrower by the pressure upon it of the dilated pulmonary artery, the loud systolic murmur was generated within the left ventricle. The patent foramen ovale was incapable of causing it. The dilated pulmonary artery probably did not of itself cause a systolic murmur, although its thickened valves may possibly have contributed to the development of such a murmur. Beyond alluding to the bicuspid valve of the aorta this circumstance calls for no comment other than that where bicuspid semilunar valves are met with in the pulmonary artery or aorta the malformation is usually due to two of the segments of the valve coalescing so as to form one large segment. Such valves are said to exhibit a great tendency to undergo sclerotic change and to result in regurgitation. Neither of these events occurred in the aorta of the patient alluded to. The only published case bearing any resemblance to the above that I have been able to lay my hands upon is one reported by Lawrence Humphry in Allbutt's "System of Medicine," vol. v., p. 707—viz., a patient under the care of Dr. Greenfield in whom the heart was enlarged, especially the right ventricle, the two auricles communicated freely, the septum between the ventricles was complete, the left ventricle was hypertrophied and dilated, and the aortic valve consisted of two cusps, while the orifice itself was narrowed.

Congenital abnormalities of the heart raise many important questions to which answers cannot always be returned. Two circumstances stand out prominently in ante-natal pathology: one is that malformations of development can be produced experimentally in the embryo chick by shaking the egg, varnishing its surface, or by injecting toxins within the shell; and the other is that when the mammalian embryo is interfered with during the very early days of development the result is an abnormality, but if the experiment is made later and nearer term it is much more likely to result in disease; in other words, when a maternal malady occurs shortly after the commencement of pregnancy it is apt to cause a malformation of the fœtus, if later intrauterine disease. It depends upon the stage of development the embryo has reached and the manner in which impressions are made upon it as to whether the result is an incomplete inter-ventricular or inter-auricular septum or whether the evolution of the large arterial trunks that rise from the aortic bulb is interfered with. The septum between the ventricles grows up as early as the fourth week.

It used to be taught that the placenta is a barrier to the passage of poisons from the mother to the fœtus. Porak showed that this did not apply to some of the metallic poisons and in my own experiments of feeding pregnant animals with white lead not only did the fœtuses die in utero, but in their liver was found lead on chemical analysis. It is thus, too, with poisons of a more subtle nature. The distinguished French obstetrician Mauriceau was born with the marks of small-pox upon his body and mothers are known to have transmitted the virus to their children in utero without they themselves exhibiting the disease. Maternal rheumatic fever may be followed by fœtal endocarditis. To ante-natal endocarditis must be attributed some congenital defects of valves, such, for example, as when they are found glued together in infants who have died shortly after birth. As it is the right side of the heart that has the greater amount of work to do in the fœtus, judging from its thicker walls, so it is therein we look for, and where we usually find, evidence of the consequences of ante-natal endocarditis.

Some congenital defects are more serious than others. It is impossible for the fœtus to live outside the uterus with some of them. Free communication between the auricles or between the ventricles is not necessarily attended by danger to life, for the circulation is still capable of being carried on and considerable length of years may be reached without any symptoms at all. Cyanosis even may not be present. It is with congenital abnormality of the heart as with diseased hearts—the balance of the circulation has to be broken before symptoms arise. In morbus cæruleus in addition to cyanosis and clubbing of the fingers epistaxis is frequent. Gibson of Edinburgh has shown that the blood itself is altered; its specific gravity is often as high as 1070, its hæmoglobin may reach 160 per cent., and the number of red corpuscles may rise to 9,000,000 per cubic millimetre, nearly double the ordinary number met with in health. Children thus affected bear cold badly. They cannot get sufficient oxygen into their blood and consequently their body temperature is low. Not only are they cold-blooded, they are apathetic and lethargic and are with difficulty educated. Where a patent foramen ovale persists there may be no symptoms and no physical signs, but should the inter-ventricular septum be defective the circulation is apt to be impeded, for blood is thrown with considerable force into the right ventricle and distends this chamber and as a consequence there is often dyspnœa on exertion. The pathology of cyanosis is not yet quite clear. It is maintained that in congenital heart disease cyanosis is due to an intermixture of the two kinds of blood, arterial and venous, or to extensive venous congestion, and yet sometimes very imperfectly closed inter-ventricular septa are found on post-mortem examination without there having been cyanosis during life except in particular circumstances. It is a question of aeration. There is a difficulty of getting oxygen into the blood. This liquid exhibits its original fœtal characters of retaining in its hæmoglobin excess of carbonic acid. The cyanosis, it seems to me, depends rather upon the physical and chemical constitution of the blood itself than upon defective circulation or upon admixture of arterial and venous currents, for although hæmoglobin is hæmoglobin under all circumstances yet in congenital cyanosis it never becomes the typical oxy-hæmoglobin that gives the bright red hue to actual blood. As the cyanosis is most marked in those cases of congenital heart disease where obstruction to the circulation existed long before birth it would seem as if the defect in the development of the cardiac apparatus had made itself felt upon other specially related portions of the mesoblast whereby the blood corpuscles at their inception have characters impressed upon them different to the normal.

Usually there is little or no difficulty in the diagnosis of congenital heart disease. Cyanosis at birth, and persisting, accompanied by clubbing of the finger ends and a tendency to epistaxis, suggests malformation of the heart. The difficulty consists rather in diagnosing the particular kind of malformation. The area of cardiac dulness is usually enlarged. On auscultation there is frequently heard a loud prolonged systolic murmur over not only the whole of the præcordial area but the back of the chest and pretty well over the whole of the trunk. There may be a thrill, systolic in time, felt over the upper part of the area of cardiac dulness. The second sound at the base is oftener accentuated than not. Very rarely a diastolic murmur is heard at the base. These remarks apply to stenosis of the pulmonary artery and imperfect inter-ventricular septum, to incomplete inter-auricular septum attended by complications, and to patent ductus arteriosus. Where the ductus arteriosus remains pervious the rumbling systolic murmur is located mostly at the second and third left intercostal cartilages.

A good deal depends upon the nature and the extent of the malformation as to how long life will be maintained. If the defect in the heart is great the infant will probably die shortly after birth, but a patent foramen ovale or a slight incompleteness of the inter-ventricular septum is quite consistent with the attainment of great age. Several of my own patients reached the age of 40 years and presented no symptoms and had no discomfort until an intercurrent malady, like bronchitis or some pulmonary malady, developed, which disturbed the balance of the circulation. In some instances individuals who were the subjects of congenital malformation of the heart have reached the age of 70 years. Tuberculous disease of the lung is met with, particularly when there is stenosis of the pulmonary artery.

Treatment can only be conducted on general lines. Warm clothing must be worn, all violent exercise and undue exertion should be avoided, the diet should be carefully attended to, and complications should be treated as they arise.

A Lecture

ON

THE USES OF PARAFFIN IN PLASTIC SURGERY.

Delivered at the Medical Graduates' College and Polyclinic on April 3rd, 1903,

BY STEPHEN PAGET, F.R.C.S. ENG.,
SURGEON TO THE WEST LONDON HOSPITAL AND TO THE THROAT AND EAR DEPARTMENT OF THE MIDDLESEX HOSPITAL.

GENTLEMEN,—It is now four years since Gersuny of Vienna invented the injection of paraffin for the cure of certain deformities and diseases. The whole subject cannot be got into one lecture; but I ask your leave to-day to say something first about the history of this method; next, about its practice; and finally, about its results.

HISTORY.

The whole credit of the discovery of this method must be given to Gersuny and to him alone. It is true that Delanger of Tournai, also in 1899, did experiment on himself, putting a little paraffin under a scar on his arm; but the man who worked out the thing and made it known to our profession was Gersuny and nobody else. He had been making experiments, from a therapeutic point of view, to see what was the effect of the injection of paraffin under the skin of animals; and he had found that the paraffin, once set, remained as a hard nodule, giving no pain and undergoing no apparent change. In May, 1899, he was consulted by a young man who wished to serve in the army but could not hope to pass his medical examination because both his testicles had been removed for tuberculous disease. Gersuny, by the injection of paraffin into each half of the scrotum, produced the appearance of the testicles and the young man had no difficulty in passing his examination. Gersuny's second case was that of a girl who had undergone an operation for cleft palate. The operation had been successful, but the palate was not long enough to touch the back of the pharynx and she could not sound hard *g* or *k*. He made some slight improvement of her speech by the injection of paraffin into the palate, so that it was thickened and brought nearer to the posterior pharyngeal wall. His third case was of the same kind, his fourth case was a sunken cicatrix, and his fifth case was a sunken nose. He published these five cases, with a long list of suggestions for other uses of paraffin; some of them were [illegible] to nothing, but among them was [illegible]ght be possible to cure incontinence [illegible] of urine in the female, by raising hard nodules of paraffin under the mucous membrane of the rectum or of the bladder. And in 1900 he published his first case of this kind—a vesico-vaginal fistula which he narrowed and made water-tight with paraffin, after seven operations had been done to close it and had all of them failed. Then came a disaster, a case of pulmonary embolism. Pfannenstiel, on Nov. 23rd, 1900, injected 30 cubic centimetres of paraffin into a prolapse of the bladder with vesico-vaginal fistula. It does not appear that the patient was anæsthetised, but, what is still more strange, when he had injected this very large quantity of hot paraffin all at one time into the loose vascular tissues round the bladder, he let the patient get up and go home. No wonder that she was attacked by pulmonary embolism on her way to the railway station. She recovered and then they found that the injection had failed to close the fistula. This unhappy case brought the treatment into discredit for a time. But in February, 1901, Kapsammer published three cases of incontinence of urine in the female, from various causes, all of them successfully treated, and in June, Moskowicz, Gersuny's assistant at Vienna, published more than 30 cases treated by Gersuny and himself without any disaster and with a very good amount of success. Observe how wide was the range of these cases. Clefts and fistulæ were narrowed, cavities here and there were filled up, prolapses and herniæ were kept back, small-pox marks were taken out, sunken noses were remodelled, the falling in of the cheek after removal of the upper jaw was repaired, and a nerve divided for the relief of neuralgia was prevented from growing together again. This paper by Moskowicz is a wonderful instance of surgical zeal, almost of surgical extravagance, and in one or two of the cases there was more valour than discretion in the use of the paraffin. All the same, there is a long record of good and successful work, and it left not much more to be said.

That is the history of the introduction of Gersuny's discovery; and in this country the method is associated with the names of Walsham, Scanes Spicer, Ball, and Lake in London, Walker Downie in Glasgow, and Cathcart in Edinburgh. As for me, I published two cases last September in the *British Medical Journal* and to my amazement they were copied into the *Daily Mail* as a wonderful new discovery, and from the *Daily Mail* into all sorts of papers, including *Tit-Bits* and the *Woman's World*. The immediate result was that a great many cases of sunken nose came to me for treatment with paraffin; and I have already operated on 43 cases of sunken nose and three prolapses. But the whole invention of the method and its introduction into practice are Gersuny's work, and I ask you again to observe what a wide field of surgery he set himself to cover. If we could create fibrous tissue in the living body we should find a thousand uses for it and the use of paraffin is to build up in any accessible part of the body a structure that shall act like hard fibrous tissue. We may admit that the method has been carried too far in this or that case, but there remains a vast number of cases in which it has succeeded, though the usual operations of surgery had all failed or had been impracticable. It has been especially valuable in certain cases of fistula, in cases of prolapse, and in cases of sunken nose; and it is, for some of these tedious and miserable cases, a very happy discovery.

PRACTICE.

So much for the history of this method. Now for the practice of it and the rules that are to be observed in the making of these injections. Let me say, once and for all, that it is not so easy as it sounds, and that nobody ought to begin remodelling noses and bolstering up prolapses till he has thoroughly rehearsed the whole performance and has learned all the tricks of the materials that he is working with. Again and again something goes wrong just at the last moment: a syringe leaks or cracks, or the paraffin sets in the needle, or escapes above the piston, or oozes out again at the point where the needle went in, or fails to do what it ought. Let us take the whole subject in order: first the paraffin, next the syringe, and next the method of making the injection.

The paraffin, of course, must be sterilised by boiling before it is put in bottles. Everybody is agreed about that, but then comes the question, Which is the best of the paraffins that are now in use? Is it Gersuny's which melts at 104° F., or Pfannenstiel's which melts at 115°, or Eckstein's [illegible] too hot, and it has no special advantages. Gersuny's paraffin is easy to use; but I doubt whether it sets quite so quickly and so hard as it ought, and I doubt whether it would stay unchanged through a prolonged fever or a constant exposure to tropical sunshine. Moreover, there is some evidence, from experiments on animals, that it is safer to use a pure paraffin, not a mixture of paraffin with vaselin. So far as I can understand all these arguments about the different kinds of paraffin, I think that we had better use a paraffin that cannot be softened by any possible rise of the body-temperature and is not likely to burn the tissues. That is to say, it ought to have a melting-point somewhere between 108° and 115°. A point or two, this way or that, is no great matter. But where the paraffin has got to stand heavy and immediate pressure, as in the modelling of a sunken nose, there, I think, the higher melting-point is preferable. Where the strain and the pressure are less, as in the bolstering up of prolapsed mucous membrane, the lower melting-point will suffice.

Next, we must bear in mind that all paraffin shrinks when it sets. For example, the paraffin that is used for imbedding specimens, to cut sections, is always cupped and shrunk; and the same thing happens with paraffin injected under the skin or under the mucous membrane. Of course, the hardest paraffins shrink the most; but they all shrink more or less, except those that are too soft to be of general use. This natural shrinkage is inevitable; happily it comes to very little and in many cases cannot be detected.

Next, let us consider the syringe. Do we require a special syringe or can we manage with an ordinary antitoxin syringe? For the injection of paraffin into the loose submucous tissue of a prolapse an ordinary antitoxin syringe works well; but it does not work well, at least in my hands, for the remodelling of noses. In cases of prolapse there is no great pressure on the paraffin; but in nose cases there is a good deal of pressure. In cases of prolapse no harm is done by a slight excess of paraffin or by a slight inequality in the distribution of it; but in nose cases you have to be more accurate. Therefore the wiser plan is to have a special syringe. The right sort of syringe for these injections can be worked easily with one hand; it cannot inject an excess of paraffin with a jerk; it retains heat well; it does not leak; and it can be sterilised by boiling. To insure these advantages it is made with two rests for the fingers; it has a screw-nut running on its piston-rod; it is jacketed with a bit of drainage-tube; its needle is screwed on to it, not merely plugged on or attached by a bayonet-catch; there is a little leather washer (leather, not rubber) between the needle and the syringe; and the several parts of the syringe are screwed or welded together, not merely stuck together with cement. A strong, straight steel needle, one or one and a half inches long, is employed, such as is used for exploring the pleura, shortened and fitted with a screw-cap for attachment to the syringe. A very good syringe is sold by Mr. Rogers of 327, Oxford-street, W.; he also keeps the sterilised paraffins.

The method of injection is much the same whether a sunken nose is to be remodelled or a sinus is to have its walls brought into apposition or a prolapse is to be held up. You melt the paraffin by putting it in water that is well above its melting-point but not hot enough to crack the bottle. You sterilise your needles and cleanse your syringes and test them carefully. I say syringes because it is well to have two in case of accidents. Then you put your melted paraffin and your syringes in a water bath at a temperature five or six degrees above the melting-point of the paraffin. An ordinary steriliser makes a good water bath and you must secure your bottle of paraffin with a loop of wire or some such contrivance to keep it from toppling over. Everything being ready you draw up four or five cubic centimetres of paraffin; then you hold the syringe under water while you adjust the screw-nut and press out a drop or two of paraffin to make sure that it is all right; then you dip your needle for six or eight seconds into water that is boiling or just off the boil; and then you make the injection. But of course it is one thing to be working at a sunken nose and another thing to be working at a prolapsed bowel. Let me speak first of nose cases and then of cases of prolapse. Practically my experience is limited to these two kinds of cases.

1. *The remodelling of noses.*—I have now done 43 of these cases. There have been no death, no embolism, no sloughing of the skin, and no wandering of paraffin into the eyelids, and the results are permanent and they are good. In some cases the improvement is really excellent, in some it is fairly good, and in some I have failed to do much good. In a very few I am sorry that I ever meddled with the case. In more than one case a good result ought to have been obtained but was not for want of more skill and better judgment. Some cases that seemed hopeless have done very well and some that looked very easy were found to be insuperably hard. Sometimes I have been pleased and the patient has been disappointed; at other times I have been disappointed but the patient has been pleased. It is anxious work and heavy responsibility altering the shape of people's noses and the more I see of these cases the more certain I am that you cannot manufacture perfect Greek noses out of nothing and that the surgeon must be content if he succeeds in making a nose that shall be merely unnoticeable. But do not think that it is a small matter to accomplish this much. You can enable a man to get work and to get a girl to marry him and to go through life without the incessant staring and chaffing that made him always unhappy and self-conscious. Remember especially that the man in the street takes it for granted that a sunken nose is proof positive of syphilis. I will not take up your time by repeating the miserable stories that some of these patients have told me—how they are out of work and badgered and ridiculed everywhere because they are so ugly. And it is even harder for the women. Of course, in some of these nose cases one may find something to laugh at; all the same it is a tragedy and the comic element, after all, is a part of the tragedy. So one has to take these cases seriously and in the treatment of them it is wisest not to promise too much but to say that you will do your best to improve them so far that they shall be able to go through life unnoticed and free from contempt and chaff.

Now let me say something first about the different kinds of sunken nose and then about the method of injecting the paraffin in these cases. I will not describe the causes of sunken nose. Doubtless the chief causes are injury, inherited syphilis, and acquired syphilis, but there remains a set of cases where the history is of this sort, that the patient had an abscess in the nose when he was a child and then the bridge of the nose fell in or never grew up. These cases are not, I think, syphilitic and they seem to show that the nasal bones in early life may be attacked by that acute inflammation which we call in the long bones acute osteomyelitis, or acute epiphysitis. There is also another set of cases where you get no history at all. The patient was "born like it"; he "never had a bridge to his nose"; he may have injured it, but every child knocks his nose some time or other. Anyhow, there are no history of acute destructive inflammation and no evidence of syphilis, only the nose has always been flat ever since the patient was a baby. These cases seem to point to a real arrest of development either from some slight injury or from some transmitted influence of which we know nothing.

There are two principal forms of sunken nose. In one there is no bridge to the nose, the nasal bones are flat, and the whole nose is ape-like—what the Germans call a "saddle nose"; in the other the bridge of the nose is intact but the soft tissues between the bridge and the tip are sunken as though a bite had been taken out of the nose just below the bridge. Let us call the first form the bridgeless nose and the second form the indented nose. And I wish here to say that I have lately seen two cases of this indented nose, in one of which the deformity seems to have followed the ordinary operation for adenoids; in the other it followed the application of perchloride of iron to the inside of the nose to stop bleeding after an operation on the inferior turbinates. I only tell you what I was told and I cannot understand how the removal of adenoids could cause indentation of the nose; but in the second case it seems certain that the perchloride of iron had burned a hole through the septum nasi and had brought about a very ugly sinking-in of the lower part of the nose. This case where the septum was perforated leads me to speak of perforations of the septum in their relation to the use of paraffin. A small perforation, or even a perforation as big as a sixpence, makes no difference to the success of the injection. Of course, there are cases of old syphilitic necrosis with a large hole in the hard palate and all the inside of the nose wrecked and destroyed and the nose all shrunken and crumpled up where you cannot get a good result. I will speak of these cases in a minute or two, but the point which I wish to make here is that a simple perforation of the septum, even a large one, does not in any way interfere with the remodelling of the outside of the nose. So long as you can get your needle between the mucous membrane inside and the skin outside you may improve the looks of the patient. Only the skin must be loose, not cicatricial. That is the one thing more important than everything else. What is the condition of the skin? It matters little whether you are dealing with a bridgeless nose or with an indented nose; and sometimes the cases that look the worst do the best. It all depends on the state of the skin. If it is fairly loose and soft and healthy, if you can pick it up between your finger and your thumb, then you can be sure of doing good. Try raising the skin between your fingers, drawing it forward into position, and you will see in a moment whether your injection will be successful, for if you can raise the skin then the paraffin can raise the skin and keep it raised. But if the skin is tight and hide-bound and rigidly contracted, as it is in elderly people whose noses have been sunken for nearly half a century, or, still worse, if it is cicatricial and immoveably fastened by adhesions to the deeper tissues, then you will never make that patient good-looking and you are in danger of failure and great disappointment.

The most favourable of all cases are those in which there are an abundance of loose healthy skin and a fair length of face between the forehead and the mouth and a well-shaped and refined tip to the nose. The most unfavourable cases are those where the nose is shrunken, shrivelled, and cicatricial and, as it were, crumpled up by old syphilitic necrosis. Between these two extremes there are all sorts of cases: some where the nasal arch is splayed out on either side of the face, making an unsightly ridge under each eye; some where the nose is not only sunken but also crooked; some where the tip of the nose is wide and clumsy and out of proportion to the rest of the face; and some where the face is so short and square that there is not much room to work in. You may find it necessary to straighten the nose or to do some plastic operation before you make use of the paraffin, or you may have to inject the paraffin not once but twice or even three times. And you must not expect that you can work miracles. It is better to do too little than to do too much; it is better to set yourselves to make not perfect noses but unnoticeable noses. Be content if you can raise a decent-looking bridge or if you can *almost* obliterate an ugly indentation below the bridge.

I come now to the method of injecting the paraffin in these nose cases. Prepare everything very carefully and even then expect that something will go wrong at the last moment. In most cases I insert the needle low down, just above the tip of the nose, in or near the middle line, and inject upwards; for I feel sure that I cannot then wound the transverse nasal vein, nor can the paraffin run into the tip of the nose. It is a good plan to prick the skin first with a fine surgical needle set in a holder; this enables you to introduce the paraffin-needle gently and accurately. It is also a good plan just before you make the injection to dip your needle for six or eight seconds into water that is boiling or just off the boil as this prevents the paraffin from setting in the needle. The injection must be made rather rapidly, say, at the rate of one cubic centimetre every 8 or 10 seconds, so that you may get all your paraffin soft at the same time and may mould it altogether. How much paraffin does it take to raise a sunken nose? I have said elsewhere from 8 to 10 cubic centimetres. This is too much. I do not deny that some noses, even with this quantity, still remain somewhat sunken. The paraffin will not all run in and some of it is wasted and that which does run in does not produce the desired effect. These are the unfavourable cases where the skin is shrunken, hide-bound, or cicatricial, but in a favourable case where the skin is loose and healthy you may raise it satisfactorily with two or three cubic centimetres. While you inject the paraffin your assistant presses his fingers and thumbs hard and tight over the forehead, the eyebrows, the inner angles of the orbits, and the sides of the nose, keeping out the paraffin by hard pressure from these forbidden regions. You make the injection, you wait a few seconds to let the puncture become sealed, you withdraw the syringe and put it back in the water bath, then you take the nose and mould it vigorously while your assistant lets cold water trickle over it. Do not be too gentle over the moulding; squeeze and work the nose this way and that, and do not leave off for a good 10 or 15 minutes, till everything feels absolutely rigid. Then lay a mask of cold wet lint over the face and change it frequently. A few days later, if you want to add a little more paraffin, you can do it under cocaine only, but do not attempt it unless the skin be fairly loose or you will do more harm than good. If by mischance a small quantity of paraffin has run astray and has set where it ought not, and remains as a little nodule under the skin you can dissect it out like a little sebaceous cyst. I had to do this in one of my cases and it was easily done; but it would not be so easy if this mischance were to happen in the eyelid. In one of my cases, and in one only, a small abscess formed nearly a fortnight after the treatment; it looked very bad at the time but the final result is very good. In three cases the line of puncture of the needle broke down, but this is not a serious disaster. In all my 43 cases I have had no serious disaster, no sloughing or embolism, or any terrible thing to record. Only I have failed in a large number of cases to make the nose handsome and in a very few I have done no good at all. No two cases are alike. In one or two I gained something by freeing adherent points of skin with a sort of tenotomy needle; in one I gained something by inserting the paraffin needle into the nostril and making the injection from within outward. But there are cases where you cannot accomplish a good result, do what you will. You cannot raise the skin of the nose unless the skin is there to be raised and is loose enough to rise.

2. *The holding up of prolapses.*—Give me a few minutes more in which to speak of this use of paraffin. I have had only three cases, but the results were so good that the method certainly deserves consideration. My patients were all over 60 years old; one had prolapse of the bowel after excision of the rectum for cancer, one had prolapse of the bowel of 22 years' duration, and one had suffered for 28 years from prolapse of the uterus. I need not say what an amount of misery these three old people represent. And, to my amazement, they have all of them been cured. It is too soon to be sure that they will not need another injection later; but, for the present, there they are, wholly free from what had seemed incurable troubles. The paraffin, in these cases, must be injected immediately under the mucous membrane of the prolapse, so as to raise and to thicken and to stiffen it and to narrow the passage through which the prolapse comes down. With a prolapse of the bowel I think it is a good plan to take a fold of the prolapse between one's finger and thumb, and to endeavour to make two or three well-defined round masses or hummocks of paraffin which shall form a sort of valve or partial stricture just inside the anus. In a bad case you may have to inject the paraffin at diverse levels and for some distance above the anus. Of course, you do not dilate the anal opening; it is over-dilated already. Indeed, in one of my cases I combined with the injection of paraffin Mayo Robson's incision and deep suture to narrow the anal ring. Having injected the paraffin to the best of your judgment, so as to thicken and to stiffen and partly to occlude the lower two inches of the bowel, and, as it were, to produce the feel of a hard smooth growth involving half or two-thirds of its circumference and reducing its calibre, you put in a morphia suppository and keep the bowel up with a pad of wool and a T-bandage and treat the case as [illegible] operation. Of [illegible] of the anus may [illegible] say, three-quarters of an ounce or a whole ounce—and, in addition to the injection, Mayo Robson's incision. And, of course, you keep your paraffin away from the bladder and ureters and put it mostly under the posterior and lateral folds of [illegible] I think that one ought not to [illegible] atient can be made quite comfortable and content with a pessary, for there is, I suppose, a very slight risk of embolism. Perhaps this risk of wounding a vein could be met by a preliminary puncture with an ordinary needle at the point where the paraffin needle is to be inserted. The general procedure in prolapse of the uterus is much the same as in prolapse of the bowel, only, of course, it may need a larger quantity of paraffin; in my one case I used nearly two ounces. The injections should be kept away from the bladder and urethra, and during the injection into the posterior vaginal wall a finger should be kept up the rectum in order that it may not be wounded. The bulk of the paraffin should be put under the mucous membrane of the posterior vaginal wall and of the posterior part of the vaginal cervix and at the sides of the vagina. If there be an old rupture of the perineum it may need to be repaired. The success of my case astonished me, for I succeeded in making the vagina so narrow and so strong that the uterus remained high up and fixed, even during hard straining, and this in a woman over 70 years of age in whom the prolapse occurred if she only sneezed or turned over in bed. Of course, this method must not be used for women who may yet conceive and the vagina must not be so narrowed as to impede coition.

RESULTS.

The results in the only kinds of cases of which I have had experience are certainly good. I confess that in a very small proportion of the nose cases they have not been favourable, but in all save these they have been good and many of them have been very good. The prolapse cases are few but they have given excellent results. Doubtless in this or that case of sunken nose it would have been better instead of injection or before injection to do one of the plastic operations that Mr. W. J. Walsham has lately described in THE LANCET,[1] but on the whole the use of these injections has answered thoroughly well; only, to raise a sunken nose you must, above all else, have skin that is loose enough to rise. As for cases of prolapse it seems difficult to overestimate the good that can be done by this method, only it is not so easy as it sounds.

ABDOMINAL HYSTERECTOMY FOR MYOMA BY DOYEN'S PROCEDURES.

BY WALTER G. SPENCER, M.B., M.S. LOND.,
F.R.C.S. ENG.,
SURGEON TO THE WESTMINSTER HOSPITAL.

IT is some years ago that Dr. Doyen described his method of complete abdominal hysterectomy. The structures are rapidly divided between clamp forceps, a posterior flap is cut downwards into the posterior vaginal fornix, then the cervix is seized and hauled up, and the tumour is gradually made to turn a sort of somersault over the pubes. This method has seemed to me specially well suited for the cases mentioned below. In several of them the diagnosis had not been reached with any degree of certainty, in one case at any rate an erroneous one had been made, and on opening the abdomen inflammatory complications much obscured the anatomical conditions. Nevertheless, removal was accomplished with very little hæmorrhage and without interfering with the bladder and ureters. In these cases, except in one, there was no difficulty in excluding pregnancy. As regards the removal of the uterus, none of the women could possibly have had a viable child, and the occurrence of pregnancy would have rendered their case much more dangerous still. Vaginal and partial abdominal operations were out of the question. The abdominal operation at present most commonly adopted appears to be that of cutting across the cervix uteri. To do this one has to work from the pelvic wall inwards towards the cervix and in doing so branches of the uterine artery may be torn across deep in the pelvis or the ureter pushed inwards and either included in the clamp or ligatures, or indeed divided. In cutting across the cervix there is only a small communication with [illegible] aseptic beforehand. Indeed, with the vagina rendered aseptic the wider communication between it and the subperitoneal wound may aid drainage, for otherwise blood and pus may be retained owing to the narrowness of the cervical canal. In the one pregnant case, where maceration of the fœtus had already commenced, complete removal with the membranes unbroken preserved the wound from any contamination. As an additional reason for removing the cervix there is, perhaps, in some cases, a chance of the remaining cervix becoming malignant. In none of the cases could one define the cervix from the tumour with any certainty until the vagina was opened from above.

---

[1] THE LANCET, April 4th, 1903, p. 937.

The operation.—The preparation of the patient included the shaving of the pubes and the swabbing out of the vagina with perchloride of mercury through a speculum. The anæmic cases had a subcutaneous saline infusion during the operation. The abdomen was opened just below the umbilicus, the bladder being drawn up nearly to this point in one case. After a preliminary examination the patient was raised to about 30 degrees from the horizontal (Trendelenburg position) and the rest of the abdomen was well shut off. Then the broad ligament, including the tube near the tumour, or when the ovary was diseased the ovarian ligament, was divided between clamps on each side. The tumour having been lifted out of the pelvis and drawn forwards as much as possible, a cut was made with blunt-topped scissors in the middle line behind the tumour through the peritoneum. Keeping close to the tumour, partly by cutting, partly by blunt separation, the posterior vaginal fornix was opened. Then the volsella seized the vaginal portion of the cervix and drew it upwards. Clamps were thereupon applied to the vaginal fornix laterally, then anteriorly, and after cutting it away the cervix could be drawn further upwards and the finger could commence to separate the bladder from the tumour by working from below upwards. The separation of the bladder seems so much more easily done in this way than from above downwards. Having reached this stage, on each side the base of the broad ligament forms a tense band reaching upwards to the tumour which includes the stretched-out uterine artery and its branches, upon which can now be placed clamps with a certainty of securing the vessels. When lobulated myomatous masses extended into the broad ligaments they were now drawn away with the main tumour, no force being required to shell them out. The ureters did not come into view at all, remaining outside the area of operation and being pushed downwards with the bladder. The volsella holding the cervix being continually drawn upon the tumour became gradually inverted over the pubes until there remained to be cut across the reflection of the peritoneum from the bladder on to the anterior aspect of the tumour. Now followed the application of ligatures over the numerous clamps and a strip of iodoform gauze was passed downwards through the vagina until it could be seized at the vulva, the upper end of the strip lying in the subperitoneal wound just above the cut edges of the vagina. Finally, the cut edges of the peritoneum were sutured together across the pelvis in the line of the excised uterus and broad ligaments. The urine was drawn off from the bladder and after two or three days the strip of gauze was removed and not replaced. In one or two cases the bladder and vagina were also irrigated for some days.

CASE 1.—The patient was under the care of Dr. W. R. Pollock who transferred her to me. She was a married woman, aged 48 years, who had never been pregnant. Menstruation had been regular from the age of 13 years until a year previously, when it became irregular. The penultimate period occurred six weeks previously, after an interval of three months, and lasted nine days, and the last period occurred a week previously, lasting four days. About three months previously the patient noted an enlargement of the abdomen, which continued, and micturition became frequent and painful, both by day and by night. The abdomen presented a central rounded elastic tumour corresponding to that of a sixth months pregnancy, with a lobule on the right side. The whole cavity of the pelvis appeared to be filled by a tumour. The os presented downwards and forwards; in front the finger could be passed up behind the symphysis. The tumour in Douglas's pouch felt hard and knobby. After opening the abdomen the omentum was found to be adherent to the tumour and was separated. A bluish-walled cyst next came into view and this proved to be a right-sided ovarian cyst which was tapped. It was then difficult to define the tubes except as swollen masses buried in adhesions. The right ovarian ligament was divided between clamps on the left side of the broad ligament, leaving *in situ* the left ovary and part of the tube. Then the uterus was removed. It was much enlarged by intramural fibroids and subperitoneal fibroids had extended laterally outwards into the broad ligaments. The cyst was a multilocular ovarian cyst with intracystic growths and highly vascular intercystic tissue. The patient recovered without incident except for a little discharge from the lower end of the abdominal wound.

CASE 2.—The patient, aged 46 years, was admitted to the Westminster Hospital and was transferred to me by Dr. Pollock. She was a married woman who had never been pregnant. She had menstruated regularly from the age of 16 years until three months previously, the quantity always being excessive. She first noticed a fulness of the abdomen, causing her to become short of breath, also pain in the left iliac region and bearing-down pain. For three weeks she had had painful micturition. The urine was small in amount, dark-green, and offensive. Shortly before admission she had a severe attack of metrorrhagia. On admission she was passing urine frequently, about one ounce at a time. The bladder was found to be greatly distended, containing two and a half pints of foul urine with much mucus and pus. The pelvis was filled by a firmly fixed hard tumour and the cervix could not be distinguished. On opening the abdomen a globular tumour about four inches in diameter was found wedged into the pelvis, with the bladder in front and above. Both ovaries were normal and were left *in situ* by dividing the broad ligaments. The tumour could not be distinguished from the cervix uteri until after removal, when the latter was found at the lower pole of the tumour. The bladder was densely adherent and was only separated from below upwards by using great care. After the operation the bladder was regularly washed out at first, there being a little blood in the urine, but she was able to leave the hospital wearing a belt three weeks after the operation.

CASE 3.—This patient was under the care of Dr. F. Norman. She was a married woman, aged 44 years, who, although long married, had never been pregnant before. She had been regular as regards menstruation until five months previously. She consulted Dr. Norman for an abdominal tumour and difficulty in passing urine and he diagnosed a retroverted gravid uterus with a large fibrous tumour above and in front of it. She was afterwards seen by an obstetric physician who said that she was not pregnant but had a fibrous tumour of the ovary. On opening the abdomen the bladder appeared containing a little urine. Behind this was a tumour of the size of a child's head buried in adhesions which was shelled out. This exposed a gravid uterus wedged into the pelvis corresponding in size to a four or five months pregnancy and the shelling out of the fibroid had left a large raw area involving deeply the uterine wall. Both ovaries were cystic and of the size of hens' eggs, the whole being surrounded by adhesions, but after dividing the ovarian ligaments I was able to remove the uterus. On laying it open a fœtus—beginning to macerate, of about four months—was found. The patient recovered rapidly. Afterwards she complained of climacteric symptoms but these ceased on treatment.

CASE 4 —The patient, aged 34 years, unmarried, had been seen by Dr. Dring, Dr. W. E. Passmore, and Dr. G. Norman. She had always had irregular menstruation and this had ceased for three months. An enlargement of the abdomen had been noted for a year and more recently attacks of abdominal pain, often very severe, until at last she was obliged to give up her work and go to bed. The abdomen was extremely painful and could not be handled much, but a tumour was obvious rising from the pelvis, filling the lower half of the abdomen and extending rather higher on the right side nearly, but not quite, up to the liver. It was dull to percussion and very tense, the umbilicus was bulging, and the flanks were resonant. Per rectum a tense swelling was felt. I thought that the tumour was an ovarian cyst complicated by serous peritonitis and anticipated extensive adhesions. On commencing the operation a little free fluid escaped and then the incision was extended to about eight inches. Not a single adhesion or sign of past peritonitis was noticed. Both ovaries were enlarged and cystic and were included in the removal. There was a small unaltered uterus buried in the lower part of the tumour, whilst the whole tumour formed much the shape of, but was larger than, a uterus at term and the total weight was 6½ pounds. Recovery ensued without incident and she returned to her work.

CASE 5.—An unmarried woman, aged 36 years, was admitted for a supposed iliac abscess following old-standing hip-joint disease. The patient, who had a strong tuberculous history on the mother's side, had, when aged 14 years, fallen on the hip; a swelling followed and for this and subsequent recurrences 17 operations had been done on the left hip. Healing finally occurred six years previously; since then the patient had had a flexed and adducted hip surrounded by scars but which allowed of walking two miles at a stretch. Her left knee had also been affected and was ankylosed in extension. About six months before the patient was ill for eight weeks with a "chill," the temperature reaching 103° F. Five weeks before she again had fever with a temperature of 104° when a swelling was found for the first time in the left iliac fossa. She had been in bed since. Menstruation had always been regular; the last occasion was just before admission, with some pain. The patient's appearance corresponded to the fair type of scrofula and she was slightly jaundiced. Nothing abnormal was found in connexion with the heart, the lungs, or the urine. During the week she was under observation the temperature was always between 100° and 101° at night and not below 99° by day. The right and left iliac regions were very tender to palpation; in the left iliac region a smooth tense swelling could be detected with some intestines over it and the swelling appeared to be continuous with a bulging into the vulvar orifice and higher up was to be felt through the rectum. The right side was so tense that nothing could be made out. The operation was begun by an incision in the left linea semilunaris and the first thing reached was a hard mass continuous with the uterus; next an ovarian cyst was found of about the size of a goose's egg. The right ovary proved to be normal but the uterus, buried in peritoneal adhesions, was a mass of fibroids, subperitoneal, intramural, and submucous, and was removed with the left ovary and tube, whilst the right was left. Nothing was found connected with the hip and the operation wound healed without any complication. 15 days after the operation the patient had a sudden rigor with some jaundice [illegible] k later, but after- [illegible] She was in good [illegible] *was a very per-* [illegible] le attacks beforehand may have been due to pelvic peritonitis, but they may also have been occasioned, as undoubtedly was the case after operation, by biliary inflammation.

Case 6.—This patient had been under the care of Mr. Sydney Clark of Leeds, who advised operation some time ago, and then under the care of Dr. F. Norman. She was a married woman, aged 36 years, who had had two children, the last five years before, but no subsequent pregnancy. Dysmenorrhœa and menorrhagia became so severe that she was examined under an anæsthetic some months previously. She improved somewhat under rest, but during the last three months she had had repeated attacks of metrorrhagia, the blood rapidly distending the uterus until pains started and expelled the clot. Meanwhile she had become increasingly anæmic. Extra exertion brought on a severe attack of inflammation with pain, especially in the left iliac region which at one time almost threatened to suppurate. Per vaginam a hard globular mass filled the pelvis, whilst the cervix was *displaced upwards* and to the *left side* where it was fixed. On opening the abdomen the left ovary and broad ligament were found imbedded in an œdematous mass of recent fibrous tissue, the right ovary was unaltered, and the uterine tumour was fixed down in the pelvis. The broad ligaments were first divided and then the uterus and tumour were removed, after which the left ovary was carefully examined. As it seemed likely not to be harmful and could only have been dissected out with difficulty it was left *in situ*, for it was important to finish the operation. The patient was very anæmic, but the blood lost was so very small that she quickly recovered, and on leaving the hospital a month later was already of a better colour. There was a single intramural fibroid of the size of a cricket ball bulging out on the posterior aspect of the uterus; the uterine cavity was quite normal, both as to length and character of the mucous membran [illegible] en the result of [illegible]

Case [illegible] F. W. Rix. She was an unmarried woman, aged 38 years, who had for upwards of two years noticed an increasing enlargement of the abdomen owing to a tumour, the menstruation meanwhile remaining normal. For the last three months she had had obstinate constipation, at times chronic obstruction, with some pain and vomiting. On examination the abdomen was found to be enlarged by two masses, the lower occupying the hypogastrium and especially the right iliac region. The upper mass occupied the umbilical and adjacent portions of the right lumbar and hypochondriac regions. It was partially moveable, partly attached to the lower mass by a neck, had intestines in front of it, but was free from the liver. On opening the abdomen the bladder had to be pushed downwards and then the wound was sufficiently enlarged to deliver the upper pedunculated mass; next, as both ovaries were found to be sound, the broad ligaments were divided with the tubes, the posterior vaginal fornix was opened and the cervix was drawn up. As the rest of the vaginal attachment and the base of the broad ligaments were divided internal to clamps the lateral masses were easily withdrawn with the uterus from the broad ligaments into which they had grown. The whole mass consisted of pedunculated and subsessile subperitoneal myomas, weighing 2½ pounds, around a small uterus. The patient's *recovery was entirely undisturbed.*

Case 8.—The patient was an unmarried woman, aged 34 years, who was admitted with an increasing abdominal tumour and very marked anæmia. The enlargement had been noted for several months. She had menstruated at regular intervals but had had prolonged periods and an excessive loss of blood with clots. There had been no special pain. An elastic lobulated swelling filled the pelvis and bulged into the vagina and rectum, whilst the cervix was high up in front, almost out of reach and inseparable from the tumour. An incision was made about six inches in length through a very thin abdominal wall; the uterine tumour presented whilst the bladder was well down behind the pubes. Both ovaries were cystic and enlarged to the size of hens' eggs but flattened. The uterus formed a greatly enlarged mass of separate intramural tumours of about the size of a double fist, in the middle of which was the uterine cavity, the cervix only being made out after removal. Nothing abnormal occurred for nine days after operation, although the patient was very weak and anæmic. The abdominal wall had been *sutured by a row of kangaroo-tail tendons closing the peritoneum*, another row united the recti, and the skin was sutured by silk. On the ninth day the skin sutures were removed and the wound, apparently uniting perfectly well, was dressed with gauze, wool, and a many-tailed bandage. The abdomen was quite flaccid and the bowels had been moved regularly from the second day. As it turned out I ought to have supported the abdominal wall with strapping in this instance, for about 12 hours later the patient, who had meanwhile been lying in bed without cough and had not had the bowels moved or had attempted to sit up, complained of pain in the chest and of a feeling that the intestines were coming out. Mr. G. L. Bunting, the house surgeon, found about two feet of intestine prolapsed through the upper part of the wound and already adherent to the dressings. He washed the intestines and breaking down more of the wound replaced the intestines and united the wall by deep interrupted sutures of fishing gut. No general peritonitis followed but a pelvic swelling, which was doubt- [illegible] meanwhile her general strength improved and the anæmia gradually diminished

The three points in favour of the measures adopted are:—(1) the certainty of the procedure in spite of inflammatory complications or the main tumour obscuring details; (2) the certainty of securing the uterine artery at a good distance from its origin; and (3) the ease with which the bladder and ureters are pushed out of the way of the field of operation.

Brook-street, W.

A CASE OF ACUTE BULLOUS ERUPTION AFFECTING A BUTCHER.

By ARTHUR S. MORLEY, F.R.C.S. Eng., L.R.C.P. Lond.
and
G. H. RANSOME, M.R.C.S. Eng., L.R.C.P. Lond.

The following case, resembling as it does in many particulars a series of cases occurring in butchers which was described by Mr. George Pernet and Dr. W. Bulloch,[1] appears to us to be of some interest and importance.

The patient was a butcher, aged 26 years. With regard to his previous history, five years before he had "blood poisoning in the leg caused by bad drains." He had had no other illness worthy of note. He had never had any venereal disease. He was accustomed to eat large quantities of meat and had lately kept rather late hours. He did not take much alcohol. He frequently pricked his fingers in hanging up meat and "for some days" had had a suppurating wound on his left middle finger. For three days he had noticed a circinate scaly patch on the back of his left forearm and thinking that it was ringworm he had "blistered it with some stuff from the chemist's." He consulted us on Feb. 9th and the following are our notes of his case. The patient was a very plethoric young man. There was a small unhealthy-looking suppurating wound on the side of the left middle finger. On the back of the left forearm was a circinate scaly area of about the size of a shilling presenting several points of pus. On microscopical examination of some broken hairs removed from the patch no ringworm fungus could be discovered, but as the lesion was clinically indistinguishable from ringworm it was treated as such, being swabbed over with pure formalin and dressed with white precipitate ointment. The wound on the finger was also cleaned and dressed with the same ointment. A mixture containing perchloride of iron and sulphate of magnesium was also prescribed. On the 11th there were blisters all round the patch with slight dermatitis. There were much irritation and pricking. The wound on the finger still looked unhealthy. On the 12th the dermatitis was spreading. The vesicles had burst, leaving a raw surface. On the 14th there were inflammation and swelling of the whole of the back of the left forearm. Lead lotion was applied. On the 20th there was slight erythemato-dermatitis in the bend of the elbow, spreading up on to the arm. The forearm was rather less inflamed. On the 22nd there were inflammation of the entire skin of the forearm with much œdema, slightly raised punctate erythema up the arm and on the chest, and slight erythema also on the *right* wrist. Considerable pain was present. The temperature was normal. An internal angular splint and hot boric fomentations were applied to the left arm. On the 23rd the dermatitis was spreading over the trunk. The evening temperature was 99° F. The patient was ordered to bed. Five grains of calomel were given at once and 10 minims of antimonial wine three times a day were prescribed and the arm was placed in a continuous boric bath. On the 24th there was a general eruption over the whole body. On the right forearm the erup erous resembled variola in the pustular stage; there were di wnwards shotty pustules, surrounded by areolæ of intense ulva, the redness. On the left forearm the epidermis was a und just leaving a raw bleeding surface, although the general i nt edges mation was rather less. On the left arm was a pa elvis in eruption with a few small scattered bullæ. On the s The and palms there were a few pustules and bullæ. On three neck were strings of vesicles and bullæ, varying in size fro In that of a large pin's head to that of a threepenny-piece, along ted the course of the descending superficial cervical nerves. There were also a few vesicles on the scalp. There was intense general erythematous dermatitis, especially over the chest. None of the bullæ were larger than raisins and many were flat-topped. There was a good deal of fœtor noticeable, particularly about the left forearm. The patient's general condition remained good. His temperature was 99·4°. The urine was normal; no albumin or sugar was present. On consultation with Dr. W. M. Crowfoot of Beccles creolin lotion (2 to 12 ounces) with liquor calcis was applied. On the 26th there was slight improvement. The pustules were drying up. There was still much general dermatitis. The temperature was 98·6°. There were some sweating and great irritation at night which disturbed sleep. The creolin seemed to allay the irritation. On the 28th the patient was improving. The vesicles were drying up. There were, however, some semi-purulent bullæ on the dorsum of the hands and feet. The original wound on the finger was not yet healed. There was much coarse general desquamation. The patient complained of a general feeling of weakness and malaise. The temperature was subnormal. The tongue was clean. Some of the serum and pus from the bullæ and pustules was drawn off and sent to Dr. Bulloch for bacteriological investigation. The antimony was discontinued and an effervescing quinine mixture was substituted and daily sponging with oatmeal and water was ordered. On March 3rd the patient was improving steadily but the original wound on the finger still discharged. There were a few discharging blebs about the ankles. His general health was improving. On the 6th there were impetigo-like scabs about the legs and knees. A boil had formed over the sacrum. The wound on the finger had now completely healed. On the 10th the patient was still desquamating freely. There were a few crusts and scabs on each leg. Three boils had formed in the axillæ. The patient was now a good deal thinner and had lost his plethoric appearance. From this time he made an uninterrupted recovery and is now completely well again.

---

[1] British Journal of Dermatology, May and June, 1896.

Remarks.—The case was one which presented a good deal of difficulty in diagnosis. At first we were inclined to attribute the dermatitis to the use of pure formalin to the patch on the forearm. But when the generalised eruption appeared on Feb. 24th this diagnosis had to be reconsidered as it is difficult to imagine how a purely local application could give rise to such a general and varied eruption. The true significance of the septic wound on the finger then occurred to us and the similarity of our case to those collected by Mr. Pernet and Dr. Bulloch[2] was apparent. The cases which they described resembled ours in that they all occurred in persons whose occupations brought them into contact with recently killed animals and in most of them there was some small septic wound or whitlow to act as the *fons et origo mali*. In Mr. Pernet's own case[3] the lesions, although much more severe, were very similar in character and distribution. There were, however, much more pyrexia and general disturbance, and the case ended fatally. Eight cases are described, all of which occurred in butchers. Of these four had septic wounds about the hands, and in the others no mention is made of this point. The incubation period in all the cases was long and the eruption, when it started, rapidly spread all over the body. All these cases occurred in adults between the ages of 17 and 33 years. In none does syphilis appear to have played a part.

Nine other cases are also collected; in six of these wounds had been sustained either from bites of animals or during occupations involving the handling of carcases. Six cases recovered and three ended fatally. In Mr. Pernet's own case Dr. Bulloch isolated and cultivated a "diplococcus resembling the gonococcus but somewhat larger." These organisms were found in the original wound in the unruptured bullæ and (post mortem) in the lungs. In the present case Dr. Bulloch very kindly undertook the examination of the serum and pus but failed to find any organisms resembling those which occurred in Mr. Pernet's case. A pure culture of staphylo orresponding albus was obtained: as this is the
pregnancy and the she und in the normal epidermis it

CASE 4.—The patien ut the points of similarity, on the
seen by Dr. Dring, D ently striking. Another somewhat
s She had alway tion has been described by Duhring under
the ceas me of "dermatitis herpetiformis," and at the discussion on this disease Dr. T. Colcott Fox stated that many of the cases started in lesions closely resembling those of herpes and tinea circinata,[1] and our case falls in line with this description. The same condition has also been described under the name of "*pemphigus en petites bulles*," and Dr. Crowfoot, who saw our case in consultation with us, said that it was similar to a case, which had been under his care, in which this diagnosis had been made. It is a point of some interest that the patient in this case was a tanner who would of course come into contact with the hides of animals. It would be of value to know the occupations of the original patients whose condition was described by Duhring, as it seems a rather plausible suggestion that the diseases described by him and by Mr. Pernet and Dr. Bulloch are closely connected. In conclusion, we wish to express our gratitude to Dr. Bulloch, to Dr. Crowfoot, and to Mr. Pernet for the advice and assistance which they have given us in the investigation and treatment of this case.

NATIONAL ASYLUM OF RIO DE JANEIRO FOR INSANITY.—Dr. Juliano Moreira, professor of psychiatry and neurology in the medical school of Bahia and co-editor of the *Gazeta Medica da Bahia*, has been appointed director of the National Asylum of Rio de Janeiro. This institution is to be enlarged shortly to 1000 beds, funds for the erection of the buildings being already available and the site purchased. Plans for a new epileptic ward are being prepared, while new children's wards have been already declared open.

A CASE OF BULLET WOUND OF THE BRAIN, WITH PARTIAL MOTOR PARESIS AND HEMIANOPSIA.

EXPERIMENTAL DETERMINATION OF THE LESION.

BY N. BISHOP HARMAN, M.A., M.B. CANTAB., F.R.C.S. ENG.,
OPHTHALMIC SURGEON, BELGRAVE HOSPITAL FOR CHILDREN; DEMONSTRATOR OF PATHOLOGY, MIDDLESEX HOSPITAL; EXAMINER IN ANATOMY, CAMBRIDGE UNIVERSITY; LATE CIVIL SURGEON, FIELD FORCE, SOUTH AFRICA;

AND

A. A. BRADBURNE, L.R.C.P., L.R.C.S. EDIN., L.F.P.S. GLASG.,
LATE CIVIL SURGEON, CONNAUGHT HOSPITAL, ALDERSHOT.

THE case is that of a private soldier who was shot whilst asleep in his tent in South Africa. The shot was believed to come from Boer snipers. The patient stated that from the time he turned in on the eve of the night of the incident he remembered nothing until he regained consciousness of his position in the military hospital. He then noticed that he had lost the power of movement on his right side and that he could not see objects which were situated on that side. His history shows that he was struck on the head by a bullet at 2 A.M. on Dec. 10th, 1901, and that he remained unconscious until the following Christmas Eve.

PHYSICAL EXAMINATION.

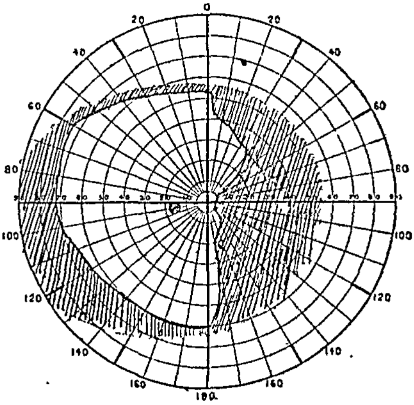
1. *The wounds.*—Examination of the head showed two wounds of the left side involving in each case the scalp and bones of the skull. Of these, one was situated at the anterior part of the parietal bone and the other in the neighbourhood of the external occipital protuberance. From the condition of the wounds there could be little doubt that the parietal wound was the site of entrance of the missile and that the occipital wound was the site of exit, for the wound of the parietal bone was a clean round hole, such as would be made by a good drill, whilst the occipital wound was a trifle larger but still fairly clean-cut hole. Both scalp wounds have healed perfectly, leaving little external trace of the injury; there is, however, some deficiency of the bone immediately beneath the scars and small depressions can be felt.

2. *The bullet.*—Whilst nothing definite could be ascertained from those who were at hand at the time of the incident the nature of was a modern small-gauge high velocity on a line coir ased bullets used by the Boers were Mauser (calibre ·275) in the vast majority of cases; there were some few other Mausers of Spanish calibre (·250), a fair number of Lee-Metford of British origin (·303), occasional Stehr of Austrian pattern (·350), and modifications of the Mauser bullet as regards its plan al sheath such as Jeffrey's sporting bullet with split sides testine en noses That the missile could not have been of surgeon, named order is evident, since the wounds, from the the upr ng nature of these bullets, would have been much the dre erious. Stehr rifles were not used in great numbers, more a large stores of this ammunition were found in the wall zine at Pretoria. It is therefore probable that the perl le was either Mauser or Lee-Metford, though which of le se cannot be determined, and it matters little for the ferences of bullet (Mauser ·275, Lee-Metford ·303) and heir effects are but small.

3. *Physical signs and visual fields.*—When the patient regained consciousness he was paralysed on the right side and could not see towards that side with either eye. In February, 1902, he was at the Connaught Hospital, Aldershot, where he came under the care of one of us (A. A. B.). At this time motor recovery was almost complete: the right arm alone remained weak but a fair range of movement was possible; the extensor reflexes were exaggerated. There was a slight degree of wasting of the muscles of the right limbs as compared with the left. In the facial region the right cheek was flatter than the left; there was weakness of the muscles of expression, especially of the corrugator supercilii, those about the root of the nose, and at the angle of the mouth. The tongue could be protruded perfectly and there was no involuntary deflection from the straight line; the uvula also acted normally. The patient did not at times speak plainly and said that he was occasionally at a loss for a word. Each letter of the alphabet could be pronounced clearly.

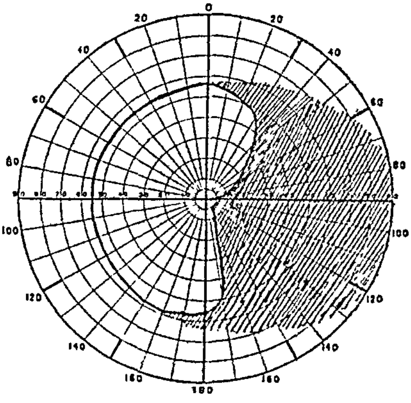
Visual acuity with each eye was full (Sn. $\frac{6}{6}$ and Jg. 1). On taking the visual fields with the perimeter it was found that the right half of each field was blind; the area within the 5° circle of central vision was intact in each eye (see *Figs.* 1 and 1A). In addition to the loss of the right half of the field on the left side there was a rim of blindness in this eye starting from the blind right half and embracing the whole of the intact area of the left half, the rim being broadest laterally (see *Fig.* 1). By the ordinary method of taking the visual field with the head directly opposite the fixation point the corresponding half of the right field showed no such rim of blindness, the field being "full" to the normal limit; to ascertain the possibility of any defect beyond the limit bounded by the projection of the nose the field of the right eye was taken in another manner. The head was placed on the rest and rotated to the left through 45°; the left eye being covered the right was diverted outwards to obtain fixation upon the spot marking the pivot of the perimeter; the nasal field was again mapped out upon a chart in which

FIG. 1.



Perimeter chart of the left eye.

FIG. 1A.

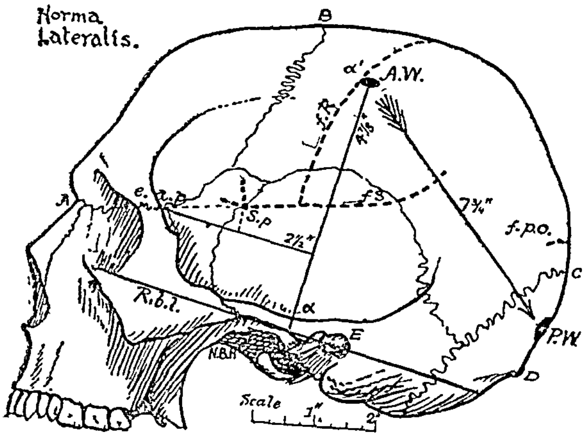


Perimeter chart of the right eye.

the limit of the field in this direction had already been marked by the like examination of another soldier (X) of the same age and similar mental capacity. It was found by this method that the periphery of the field of the patient towards the nasal side of the right eye was full, it coinciding very nearly with the control field of X. By ophthalmoscopic examination (on Feb. 15th, 1902) the retina was seen to be of a deeper red than usual, the veins were slightly engorged, and the arteries were somewhat indistinct and tortuous on the blind sides. The papillæ and maculæ were normal and the light reflexes were marked. Both pupils were of equal size and reacted equally well. Wernicke's hemiopic pupillary reaction was not present and there was no indication of "word-blindness" phenomena.

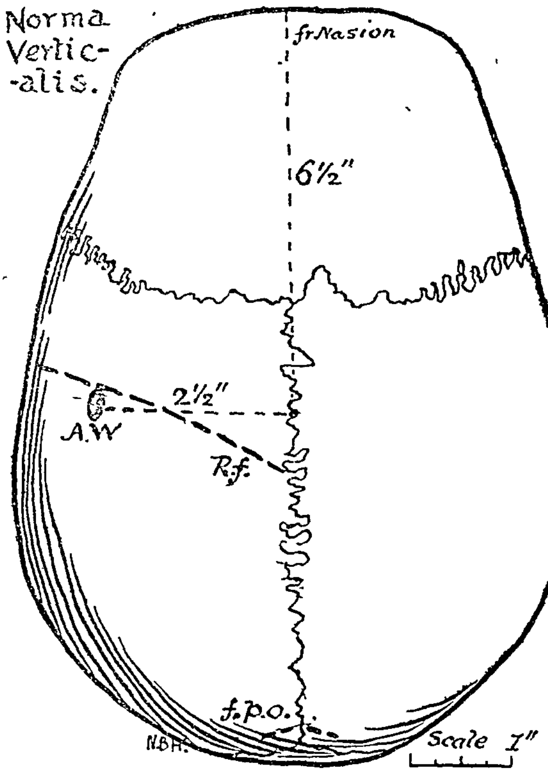
4. *Topography.*—Careful measurements of the sites of the wounds were made both in relation to Reid's base line and to the prominent bony landmarks, and the position of these was compared with the positions of the cerebral convolutions and fissures of the superficies, as obtained by the most approved schemes of measurement. (Figs. 2, 3, and 4 show the head thus mapped out.)

FIG. 2.



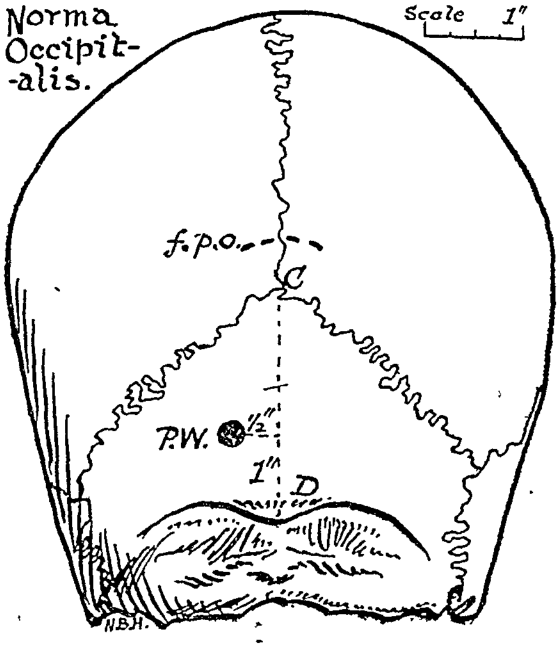
To show relation of wounds to base and other lines on the skull. See also Figs. 3 and 4. For explanation of lettering see the index at the end of the paper.

FIG. 3.



To show measurements. For lettering see the index at the end of the paper

FIG. 4.



To show measurements. For lettering see the index at the end of the paper.

(*a*) *General measurements.*—The general measurements were as follows: A from B, nasion to bregma (the bregmatic position was not certain), about 5 inches; from A to C nasion to lambda, 12 inches; from A to D, nasion to inion, 14¾ inches; from E to E, from right to left external auditory meatus over the vertex, 14¼ inches, and the distance which the vertex was situated from the nasion, 8 inches.

(*b*) *Parietal wound.*—A line (α α') drawn perpendicularly to Reid's base line to meet the centre of the wound measured 4 inches; the continuation of this line (α α') to the sagittal suture measured a further 2½ inches. This perpendicular (α α') is situated 2½ inches from the external angular process measured parallel to the base line, and at the sagittal suture 6½ inches from the nasion.

(*c*) *Occipital wound.*—The centre of the wound is situated 1 inch from the most prominent part of the external occipital protuberance (or 2½ inches up from the base line) and half an inch to the left of the median longitudinal line as continued from the sagittal suture through the lambda to the external occipital process.

5 *Relation of wounds to cerebral cortex.*—The position of the principal fissures is given in dotted lines on the same figures; they were obtained in the manner described by Cunningham.[1] A skull of similar measurements to the head of the patient was marked out with these lines and the measurements for the wounds sites, and the whole was drawn with the aid of Broca's craniograph. It was found that the parietal wound was situated just behind the fissure of Rolando on a level with that part thereof which should be immediately posterior to the bifurcation of the superior frontal sulcus to form the precentral sulcus. The occipital wound fell in the occipital lobe about the level of the calcarine fissure.

6. *Experimental determination.*[2]—As a means of checking these results, preparing a graphic representation of the lesion, and to demonstrate the actual grey areas and white tracts penetrated by the bullet the lesion was made experimentally upon a recently deceased subject (a male, aged 48 years) the measurements of whose head, as determined by the usual craniometric methods, corresponded exactly with those of the head of the patient. The subject had been dead

[2] This method of demonstrating the lesions of bullet wounds of the brain was described by N. B. H. before the Pathological Society of London in July, 1902.

about ten hours when the skin of the neck was opened in the middle line and the common carotid arteries of each side were dissected out; into each of them in turn a cannula was inserted through which about two ounces of formalin (40 per cent.) were slowly injected until the formalin escaped from the nostrils. The vessels were ligatured and the body was left for five hours. The sites of the wounds were then found by the proper measurements and marked by holes drilled into the skull. The scalp was removed and the wound areas were trephined, a fine stilette was passed from hole to hole, and over this was passed a glass tube of the same size as a Mauser bullet The skull-cap was then sawn off and the brain, which had become quite firm from the hardening agent, was removed and placed in a 5 per cent. solution of the same preservative. As regards the position of the trephine holes to the vessels on the inner surface of the skull, it was noted that the parietal wound had not cut into any large branch of the middle meningeal artery, it was well above the fork formed by its two large anterior and posterior branches, whilst the occipital hole had failed to injure either the superior longitudinal, the lateral, or torcular sinuses.

7. *The brain lesion.*—Fig. 5 is reduced from a scale drawing of the lateral surface of the left hemisphere; the probe is lying in the track of the lesion. The arrangement of the convolutions is strikingly "average" and the brain might have supplied the model for an anatomical plate The entrance wound is noted in the anterior edge of the ascending [illegible] of [illegible] es [illegible] nal convolutions, under the angular gyrus to the posterior extremity of the occipital lobe. Fig. 6 shows the mesial aspect of the hemisphere; the exit wound is noted at the posterior inferior angle of the middle occipital convolution as it blends with the cuneus. Vertical sections of the hemisphere were made at B, C, and D (see Figs 7, 8, and 9) In section B, which cuts through the ascending parietal convolution, the track of the lesion is so situated that it is distant only a few millimetres from the grey matter forming the greater part of this ascending parietal convolution and in such a manner that it must have completely cut off the communications with this area In section C, which cuts through the angular gyrus, the lesion is deeper, but here, again, it cannot have failed to cut off communications with the whole of this important area. In section D, through the parieto-occipital fissure and the apex of the cuneus, the lesion again dominates the communications to the cuneus and occipital cortex through the occipito-thalamic radiation. Thus at all points the lesion has dominated the cortex behind the fissure of Rolando; it has either directly destroyed it in its passage or else the line of the lesion is so close to it that it could not fail to have been destroyed for functional purposes by the disturbance set up by the rapid transit of a missile in such a line; further, through the greater part of its length the occipito-thalamic radiation of Gratiolet has been traversed by the lesion A more completely destructive lesion short of excision could not well be devised.

That the passage of a small gauge bullet at a high velocity

cleanly through soft tissues will produce damage over and above the direct destruction incident to its passage we have seen many proofs in the intractable neuralgia in wounds of limbs, in cases where the nerves affected could not by any means have been directly involved. In some such cases the absence of any traceable morbid condition has been demonstrated by operative examination.[3] The production of this disability in structures distant from the actual lesion has been ascribed to the shock produced by the "expanding force" of the missile. If such effects are marked in the case of passage through the soft parts of a limb, composed of comparatively coarsely organised tissues, how much greater the effect of such a force acting upon the brain—first from the blow to the skull and, secondly, from the passage of the missile through a highly organised nerve mass inclosed within an unyielding envelope.

CONCLUSIONS.

Whilst it would be unwise to base any elaborate deductions upon one set of observations there are certain points of interest which arise out of this case and the experimental demonstration thereof.

The transient motor paresis.—According to the localisation of the motor areas by Ferrier, Horsley, and Beevor the destruction of the ascending parietal convolution at the wound of entrance should have produced a serious and probably permanent paralysis. The man has early and almost completely recovered from the motor disability. This fits in with the more recent localisation of the motor areas in the anthropoid apes by Sherrington and Grünbaum[4] in which the area was bounded posteriorly by the Rolandic fissure and did not extend to the ascending parietal fissure or that part of it dipping into the fissure. The shock of the injury in the region of the ascending frontal convolution one would judge to be quite enough to account for the symptoms described. It is also noteworthy that the entrance wound is nearest the site of the arm area, in which limb there remains some slight weakness.

The hemianopsia.—The penetration of the occipito-thalamic radiation and the undermining of the angular gyrus and occipital lobes are so thorough that at first sight it would appear that no evidence could be gleaned from this case in the vexed question of the relation of psychic and perceptive visual centres to those cortical areas; also the general features of the fields of vision in the preservation of the central areas (complete within the 5° circle) and the retention of the portions supplied by the right side of the cortex are so well known as to call for no special comment. There is, however, one point of importance—the rim of blindness found along the left side of the left field, indicating the existence of a defect in the area held to be supplied by nerve fibres connected with the right cortex. How may this rim of blindness be accounted for? There is, of course, no evidence that the man's field was full in this direction prior to the injury, but an explanation obtained by a negation of this sort is hardly tenable. The matter is complicated by the fact that the blind rim corresponds to that portion of the right field normally absent—it is amblyopic on account of disuse caused by the obstructing nose; as has been stated no further diminution of this region could be discovered. The blind rim might be held to be a defect due to intraocular conditions following the injury, but there were neither ophthalmoscopic changes nor defective pupillary reaction to lend support to such a view. There remain two possible explanations. One is the hypothesis of Charcot[5] that there is a double decussation of the optic nerve and its connexions, one at the chiasma and another in the hemisphere; this scheme would supply the suggestion that the fibres derived from this blind rim were really connected with the left cortex and were destroyed within the left hemisphere after they had made their secondary crossing from the right. In the absence of any more direct and more feasible explanation the occurrence of this blind rim might perhaps be held to support Charcot's hypothesis. The second and more likely solution of the difficulty, and one which leads to a rather interesting deduction, is that the rim is the result of an injury to the right cortex. It has been noted how close to the middle line was the presumptive wound of exit, only half an inch to the left of that line. The right occipital cortex may well be held to be within the danger zone of this wound. In what way an injury occurred it is impossible to determine. Shock alone may have been of sufficient intensity permanently to incapacitate its cellular structure, mayhap the damage arose in some small hæmorrhage or in a disturbance of its venous circulation by a clot in one or other of the sinuses immediately contiguous to the wound. With an acceptance of this solution—damage to the immediately contiguous right occipital cortex—there follows the interesting deduction that the periphery of the visual field is connected with that part of the cortex situated in the posterior inferior margin of the middle occipital convolution as it blends with the mesial area known as the cuneus.

Whilst it would be presumption to base any elaborate conclusions on such evidence as this—that of a single case, and one in which an injury to the right cortex cannot be proved to exist, or existing its nature and cause cannot be determined—yet it may be noted that this deduction will very well harmonise with the generally accepted view that the central area of the visual field has its cortical connexion towards the apex of the cuneus, and support the view that the perceptive centre for vision is situated in the occipital and cuneate regions rather than in the more anterior angular gyrus. Of the psychic visual centre this case gives no information.

CASE OF A MAN BLIND FROM CONGENITAL CATARACT WHO ACQUIRED SIGHT AFTER AN OPERATION WHEN HE WAS 30 YEARS OF AGE.

By A. MAITLAND RAMSAY, M.D. GLASG.,
SURGEON TO THE OPHTHALMIC INSTITUTION, GLASGOW ROYAL INFIRMARY.

A MAN, aged 30 years, blind from birth, was brought to the Glasgow Ophthalmic Institution on Feb. 24th, 1903. He was one of a family of seven, and although, as far as could be ascertained, there was no hereditary predisposition to blindness, one sister, as well as himself, was born blind and another (who died at the age of 35 years) lost her sight when she was two years old. The rest—a brother and three sisters—are said to have been able to see perfectly well. The sister who was born blind, now 33 years of age, was brought up in the Blind Asylum, but the patient himself was allowed to run about as he pleased, no attempt to educate him having ever been made. He became, however, so familiar with the country district (a few miles from Glasgow) in which he resided that he could go about without the slightest fear; and his hearing was so acute that he knew at once if there was anything unusual on a road along which he was walking, and thus he never had any difficulty in keeping himself out of danger. The "sense of obstacles" spoken of by psychologists was indeed developed to such a degree that he hardly ever came in contact with what might be in the way; he seemed to perceive the obstruction as he approached and was thereby enabled to avoid it. As he passed along a road he could tell a wall from a hedge by the sound of the air coming through the leaves and branches of the latter. He could easily go on an errand to any house in his native village, for the resonance of his footfall—quite different in sound when he was passing a building from what it was when he was opposite an open space—enabled him, perfectly familiar as he was with his surroundings, to count the houses as he passed, and thus to turn corners and finally to stop at the one which he wanted. In a strange place, however, he could never trust himself to go about without a guide, because his sense of hearing conveyed nothing to him beyond the difference between passing buildings or open spaces, and number could not come in to render the auditory impressions definite. Experience taught him in the same manner to find his way about the garden in which he worked, and he learnt to pluck flowers, to arrange them in bunches, and to pack them in boxes for the market not only without the slightest difficulty but with very great accuracy. He distinguished different blossoms partly by touch but chiefly by smell, and by dint of asking questions he got at last to know so much about their form and colour that he could arrange them in a bouquet. He recognised the presence of strangers in the house chiefly by the sense of hearing—for example, he could discriminate persons whom he knew by the sound of their respiration, and he was at once cognisant of any breathing with which he was unfamiliar. Besides this, however, he said that if he came into the house when any strange person was there he experienced a sense of "fulness." He was unable to put this in clearer terms and the feeling may correspond to that ascribed by Wardrop in 1813 in his "History of James Mitchell, a Boy Born Blind and Deaf," to a highly developed sense of smell. Occasionally he worked in the harvest field and he could bind the corn and arrange the stooks as well as any of the other labourers. He said that he was even able to build the sheaves on a cart and naively added that although the load might not look "elegant" yet it always remained firm on the cart. At other times he assisted in trimming turnips with a large sharp knife and only on one occasion did he cut himself. In the winter he was employed by a farmer to feed cattle, and as he walked along the byre his sense of hearing guided him unerringly to the stalls where the cows stood, so that he had no difficulty whatever in carrying food to them and placing it in the troughs.

[5] McKendrick's Text-book of Physiology, 1889, vol. ii., Fig. 283, p. 550.

The eyes were small and deeply sunk and they moved continuously in the sockets and there was a very pronounced alternating convergent squint. The irides were natural, the pupils were active, and the intraocular tension was normal, but both lenses were completely cataractous. The patient was quite unable to distinguish objects, although he could tell day from night and could easily perceive a light and locate it accurately; and in this he resembled the boy Mitchell who could clearly discriminate light; but, unlike him, he does not appear to have had pleasure in its brightness, and as he seems to have had no perception of bright colours the opacity was probably more complete. As the cataract seemed to be the only obstacle to vision I resolved to operate and I extracted the lens from the right eye on March 11th and that from the left eye a week later. Prior to th

in order

Chloroforr

to control

ness proved afterwards to be very troublesome, the constant motion under the dressings causing so much irritation that the bandage had to be removed and dark spectacles substituted. Both lenses were small and shrivelled and the nucleus of the right was calcareous. For about ten days after the operation on the left eye the patient appeared to be quite dazed and could not realise that he was seeing. The size of everything in the ward seemed to be very much exaggerated and on that account he had great difficulty in interpreting what he saw, but as he is inquisitive and has a keen desire for knowledge he took from the outset a most intelligent interest in his own case and asked numerous questions of his fellow patients. The first thing he actually perceived was the face of the house surgeon. He said that at first he did not know what it was that he saw, but that when Dr. Stewart asked him to look down the sense of hearing guided his eye straight to the point whence the sound came, and then, recalling what he knew from having felt his own face, he realised that this must be a mouth, and that he must be looking at a face. Once he properly understood what vision meant he made very rapid progress and his extraordinarily retentive memory enabled him to take full advantage of everything that he was

for the first time also became aware of the little red band in the centre and at once called attention to it. When he was shown a bunch of daffodils he recognised them by their smell and immediately said that they must be yellow. The colour that took him longest to master was green, but he can now name all ordinary tints readily and correctly. His difficulty with green is hard to explain unless it be that with green he has no smell-association such as he had with coloured flowers. Unlike Locke's blind man, who imagined that "scarlet was like the sound of a trumpet," he does not seem to connect any distinct ideas with particular colours except that he said that red gave him a feeling of pleasure and that the first time he saw yellow he became so sick that he thought he would vomit. The latter feeling, however, has never recurred.

He rapidly learned the letters of the alphabet and figures and he will soon be able to read and to reckon. From the very first he saw everything in its actual position, showing that the retinal inversion of a picture is interpreted psychically without any education.

One of the things that gave him peculiar pleasure was looking at the face of a watch which he had borrowed from a fellow patient. Within a day or two of his having got the loan of it he astonished me by announcing that he was able to tell the time. When I asked him how he had learned so quickly he explained that he did not understand the figures on the dial, but he had been told how to count the hours and that each space between the "black marks" meant five minutes. When asked to distinguish between a ball and a toy brick he looked at them attentively for a considerable time, his hands meanwhile moving nervously, as if he were trying to translate what he saw by comparing it with an imaginary tactile impression, and then he described both correctly. He explained that he was so much in the habit of handling objects that he had come to have a "notion in his mind" regarding the form of things. He could count accurately after he had looked at objects one by one and seemed to derive much help in his calculations by pointing with his finger. Here again he seems to translate touch into vision and to arrive at a perception of the whole through the perception of the individual parts. He cannot take things in at a glance. He does not see the passers-by on the opposite side of the street quickly. He looks most intently and moves his head backwards and forwards and from side to side as if trying to get a view of them all round before he can make up his mind what he is seeing; in a room, however, he can distinguish things much more quickly. With any complex outline, however, or group of outlines, he still has considerable difficulty, though pictures are no longer to him, as they were at first, mere masses of confused colour.

He was able to estimate size and distance more readily than might have been anticipated, although he said that he felt that if he were out of doors by himself he would be "wandered." From the time he got out of bed after the operation he could guide himself with ease through a doorway and walk about on the level, but he had considerable difficulty in ascending a stair, because the steps seemed so high that to begin with he raised his foot much farther than was necessary and without meaning to do so went up two steps at a time. Whenever he discovered his mistake he began to pay attention to the rise of each and he has now no difficulty in estimating their height. This, of course, was part of his difficulty of judging distance, though when he first looked out of a window on to the street and saw the pavement below he said that he felt that if he had a stick he should be able to touch it and thus he had not the feeling recorded of the boy operated upon by Cheselden in 1728 who thought that all objects he saw "touched his eyes," just as he had formerly got his impressions of things by pressure against the skin. Unlike him, also, the patient did not retain his faculty of moving easily about in the dark. Before the operation he could guide himself fearlessly through a ward without coming in contact with the beds or any other obstacle that might be in the way, but since he has been able to see he says that he has lost all that feeling of confidence and when his eyes are shut he is afraid to move and is impelled to open them to ascertain where he is going—so much so that he does not know what he would do if he again became blind.

The squint and ocular restlessness are less pronounced than they were, but the patient has still very little control over the movements of the eyes. When he is requested to look in any particular direction he is unable to cause the ocular muscles to do what he wishes, and the balls oscillate and one or other turns inwards to such an extent that a portion of the cornea is hidden by the inner canthus. This want of control renders it very difficult to make a satisfactory ophthalmoscopic examination, but as far as can be made out the fundus oculi is normal; indeed, the functional activity of the optic nerves since the cataracts were removed is very remarkable and is in striking contrast to the purposeless muscular movements. Disuse has crippled the function of the latter, but seems to have had but little effect on the activity of the former. The eye is a receptive organ and the light that gained access to the retina through the opaque lens proved stimulus sufficient to maintain the optic nerve in health, while the want of visual power deprived the coördinating centre in the brain of all stimulus to develop and hence the ocular muscles are not trained to obey the dictates of the will

I am indebted to Mr. W. G. MacDonald, one of my students, for bringing this case under my notice.

Glasgow.

SOME OBSERVATIONS ON THE BLOOD GASES IN DIABETES.

BY A. P. BEDDARD, M.A., M.D. CANTAB.,
ASSISTANT PHYSICIAN, GUY'S HOSPITAL; PHYSICIAN, WEST LONDON HOSPITAL;

M. S. PEMBREY, M.A., M.D. OXON.,
LECTURER IN PHYSIOLOGY AT GUY'S HOSPITAL;

AND

E. I. SPRIGGS, M.D. LOND.,
PHYSICIAN TO OUT-PATIENTS TO THE VICTORIA HOSPITAL FOR CHILDREN, CHELSEA, AND TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA-PARK; DEMONSTRATOR OF PHYSIOLOGY AND GULL RESEARCH STUDENT IN PATHOLOGY, GUY'S HOSPITAL.

(From the Physiological Laboratory, Guy's Hospital.)

Minkowski and Stadelmann were, so far as we know, the founders in the early "eighties" of the view that in diabetic coma we have to deal with an acid intoxication. In the 20 years which have since elapsed this view has steadily gained ground.

It has been shown by Walter that a condition of unconsciousness with deep respirations can be produced in herbivora by the action of acids put into the stomach, and in these animals the alkalinity of the blood was diminished and its content of carbon dioxide was reduced from 32 to 2 or 3 volumes per cent. In carnivora similar results have been obtained though with less ease, owing to the chemical mechanism by which flesh-eaters are able to neutralise considerable quantities of acid by the production of ammonia. In man it is known that the alkalinity of the blood is diminished in diabetic coma and Kraus (confirming Minkowski) found the CO_2 content of the blood constantly low in 13 cases of diabetic coma. The average was about 15 volumes per cent., with a maximum of 19·8 and a minimum of 9·8 volumes per cent. In some of these cases titration of the blood was carried out and the alkalinity was found to be depressed.

We have made estimations of the carbon dioxide in the blood and its alkalinity in 23 samples of blood from 15 cases, eight being cases of diabetic coma, three of diabetes without coma, and four being from cases of œdema of the lung, pancreatic disease, pernicious anæmia, and ascites respectively. We have also estimated in eight cases the carbon dioxide in the urine and in six cases the capacity of the blood and urine to take up that gas. In two of the cases of diabetic coma the ammonia, the oxybutyric acid and acetone, and the total nitrogen in the urine were also estimated daily, as well as the nitrogen in the food. Histological examinations of the pancreas have been made in five fatal cases.

The gases in the blood were estimated with Hill's blood pump, five or more cubic centimetres being taken for the analysis from a vein by means of an antitoxin syringe. In several cases duplicate estimations were also made with the apparatus of Barcroft and Haldane. The alkalinity of the blood was estimated by Wright's method and is expressed below in terms of normal alkali. The average alkalinity of healthy serum corresponds, according to Wright, to about $\frac{N}{30}$ NaOH. In our non-diabetic cases it has been rather higher—e.g., from $\frac{N}{25}$ to $\frac{N}{30}$.[1]

We are deeply indebted to the physicians of Guy's Hospital for permission to investigate their cases and especially to Dr. Newton Pitt under whose care were five of the patients.

An account in full of the observations, which commenced last October and are still in progress, will in course of time be published. The accompanying table gives some of the more important figures which have been obtained.

TABLE OF RESULTS.

Case.	Remarks.	Date.	Carbon dioxide in the blood (volumes per cent.).	Alkalinity of the blood.	Total carbon dioxide in the urine (volumes per cent.).	Saturation capacity for carbon dioxide of the blood (volumes per cent.).	Saturation capacity for carbon dioxide of the urine (volumes per cent.).
1	Diabetic coma.	Oct. 14th, 1902.	13·0	$\frac{N}{70}$	—	—	—
	After alkali administration.	Oct. 15th, 1902.	16·8	—	—	—	—

15	Diabetes.	May 6th, 1903.	52·0	$\frac{N}{25}$	—	—	—

---

[1] Some of our results were brought before the Medical Research Society on Feb 18th last and they are referred to in THE LANCET of March 14th, p. 715, in a paper by Dr. Hale White.

It will be seen from the table that in all the cases of diabetic coma which had not been treated with alkali the quantity of carbon dioxide which could be extracted from the blood was half or less than half the normal. The usual figure given for healthy venous blood is from 40 to 50 volumes per cent. In the blood of the non-comatose patients there was less CO_2 than in normal blood but more than in coma. In this series the depression of the alkalinity of the blood and the diminution in the CO_2 content run approximately parallel except when sodium carbonate or bicarbonate had been given. In the diabetic cases diacetic acid and acetone were present in the urine. The quantity of ammonia is usually regarded as a rough guide to the amount of oxybutyric acid and diacetic acid in the urine, though this assumption is not now without its objections. In two cases direct estimations were made of the oxybutyric acid, acetone, and the ammonia. The proportion of the total nitrogen excreted as NH_3 was high, varying from 12 to 25 per cent. In one case this high proportion was diminished by giving alkali and in another it was not.

The theory has been advanced, and is current to some extent, that in diabetic coma the blood is unable owing to its diminished alkalinity to take up the normal amount of CO_2 and thus that the tissues are overcharged with this gas. We have made four observations upon the tension of CO_2 in the blood of two cases, one of diabetes and one of diabetic coma. We have not found the amount of the gas in the urine of diabetes to be above normal. Complicated physical and chemical points are involved in the interpretation of this result, but it certainly lends no support to the theory that the tissues, in contact with which this urine has been lying, are loaded with an excess of CO_2. We have also passed CO_2 through diabetic blood and urine. In each case the fluid was able to take up a large quantity of the gas and there appears to be no physical disability of the blood to take up more CO_2.

As against the view that the tissues are loaded with CO_2 more favour has been given on the continent to the conception that in diabetes, owing to the acids produced by the morbid metabolism, the cells of the body are (from deprivation of alkali) unable to carry on the usual oxidative processes and that in coma this inability to utilise oxygen becomes acute and the cells, including those of the respiratory centre, are in a state of oxygen starvation, although there is plenty of oxygen in the blood.

From the consideration of the above experiments and from others now in progress we think that in diabetic coma the respiratory symptoms are not entirely to be explained by the assumption of a chemical disability of the blood to combine with carbon dioxide.

SURGICAL EMERGENCIES IN GENERAL PRACTICE.

BY GEORGE A. CLARKSON, F.R.C.S. ENG.

THE two following cases afford good examples of acute abdominal conditions requiring active surgical interference.

CASE 1.—The patient, a man, aged 49 years, was first seen at 2 30 P.M. on Feb. 1st, 1903. He was lying in bed, evidently in considerable pain and with an anxious expression. Asked what was the matter he immediately pointed to a hard semilunar swelling of the size of an orange immediately to the left of the umbilical cicatrix. The history was to the effect that he had not been well for some days, being troubled with aching in the limbs, cough, and wheezing. Not feeling any better that morning he had stayed in bed and about noon, during a violent fit of coughing, he felt a sudden pain and almost immediately noticed the swelling in question. Before this took place the bowels had acted naturally. He had not vomited at all, but he complained of increasing pain in the hernia, which he described as getting harder and harder. An operating table was improvised without delay in an adjoining room and within the space of an hour the operation was begun. The patient was a particularly bad subject for an anæsthetic as, in addition to some bronchial catarrh, his face was very congested from dilated venules, his arteries were thickened and rigid, and some years previously he had suffered from acute rheumatism with cardiac complications. Ether was the anæsthetic given. A free incision was made over the hernia and the sac was rapidly and freely opened. It contained much fluid under considerable tension and a loop of very congested small intestine tightly gripped at the neck of the sac which was quite small. The hernia was quite recent. There were no adhesions and no omental lining to the sac. The stricture was divided in an upward direction, the bowel was reduced, and the sac was stripped up to the ring, ligatured, and cut off. The opening in the rectus muscle was then closed with strong silk and the wound was sewn up. Except for some bronchitis, which was troublesome for the first two days, the patient made an uninterrupted recovery. The stitches were removed on the tenth day and at the end of a fortnight the patient was able to get up.

Two interesting points about the case are: (1) that four hours had intervened between
the time that the sac was op
gut was very congested and
ing had occurred.

CASE 2.—The patient was a well-nourished and healthy-looking boy, aged two years. For some two or three months he had had occasional attacks of abdominal pain believed to be due to flatulence. On the evening of April 2nd, 1903, he was seized with sudden pain in the abdomen which made him scream out and very shortly afterwards he passed a considerable amount of bright blood per rectum unmixed with mucus. When seen shortly after this had occurred the child was quite collapsed, the pulse was rapid, and there were evidently occasional paroxysms of pain. The abdomen was rather distended and rigid so that nothing pointing to the exact condition inside could be made out. The rectum contained a little bright blood and nothing abnormal could be felt in it. On the following morning the child was obviously worse, paroxysms of pain occurred about every quarter of an hour, the pulse was very rapid, and the temperature was subnormal. During the night vomiting had commenced and had continued at short intervals. Nothing further was disclosed by palpation of the abdomen or by rectal examination. The child being obviously very ill indeed an operation was advised. This was carried out in the afternoon under chloroform When the abdominal walls were well relaxed under the influence of the anæsthetic a careful palpation revealed no evidence of intussusception or the presence of any swelling at all. The abdomen was opened below the umbilicus and the distended intestines were received into a warm sterilised towel. There was a little free fluid in the peritoneal cavity. On sweeping the hand under the liver a loop of small intestine was separated and brought out, which disclosed the site of the trouble. At the apex of the loop was a tuberculous ulcer which felt like a ring of cartilage let into the bowel. This had produced a local peritonitis and the loop, having become adherent somewhere under the liver, had produced an acute kink. The adhesions, which had been broken down by the hand in bringing the coil down from its original position, were very evident. There were a few large glands in the mesentery, one being of the size of a small walnut. The intestines were sponged over and returned and the abdominal walls were united in two layers with catgut and silkworm gut. The child made an uneventful recovery. The wound healed by first intention and the bowels, at first relieved by an enema, soon began to act without assistance. Careful feeding, with as much fresh air as possible, is being carried out, and as the next few months will be spent at the seaside there should be a reasonable chance of complete recovery.

Leicester.

CESSATION OF RESPIRATION DURING ANÆSTHESIA; RECOVERY AFTER ONE AND A QUARTER HOURS.

BY DAVID LAMB, M.B., C.M. GLASG.,
ANÆSTHETIST TO THE VICTORIA INFIRMARY, GLASGOW.

ON July 3rd, 1902, a well-built man, aged 26 years, was operated upon by Mr. A. E. Maylard on account of acute inflammatory mischief in the left mastoid region. On this occasion chloroform was the anæsthetic employed and from an anæsthetic point of view the operation was completed without incident. On August 15th the patient was again brought to the anæsthetic room, on this occasion under the care of Mr. J. Grant Andrew,[1] acting for Mr. Maylard, and A.C.E. mixture was given by means of a celluloid modification of Rendle's mask. There was little or no excitement during the induction of anæsthesia and the moment the corneal reflex disappeared the patient was removed to the theatre, transferred to the operating-table, and his head arranged in position for the surgeon. Immediately this was done it was observed that he was apparently "holding his breath," as though during these manipulations he had been allowed to become too lightly under. The lower jaw was pulled forward, the lips were rubbed, and then with a little difficulty on account of the firmly clenched teeth a gag was introduced and tongue forceps applied, but, contrary to expectation, the spasm which affected also the muscles of the neck continued and lividity became rather too evident. The pupils, however, were well contracted but not pinhole; the pulse was steady, full, regular, and certainly not less than 60 per minute; and the corneal reflex was absent. A few turns of artificial respiration were followed by the disappearance of the lividity and respiratory spasm, for the latter being substituted a condition of simple cessation of respiration without other urgent symptom. After about ten minutes of the usual restorative measures (lowering the head over the end of the table, artificial respiration, slapping the chest with cold wet towels, inhalations from a sponge saturated with ether, and administration of oxygen) suspicion began to arise that the condition was due not wholly to the anæsthetic but to some intracranial condition, and the propriety of at once trephining was discussed. There being a little difficulty in keeping the jaw and tongue in position to maintain a free air-way the patient was surcharged with oxygen and a condition analogous to physiological apnœa induced, during which tracheotomy was comfortably performed by Mr. Andrew. No result being produced by the stimulation caused by the direct inhalation of ether vapour and oxygen through the tracheotomy wound it was then decided to proceed with the examination of the temporo-sphenoidal lobe and cerebellum without further delay. Silvester's method of artificial respiration interfering considerably with the surgeon's movements the patient was again surcharged with oxygen by this method and then direct compression and relaxation of the chest (Howard) with continuous administration of oxygen were substituted, thereby greatly assisting the surgeon Cardiac failure and lividity, however, tended to occur more readily when this method was adopted, and the operation had occasionally to be interrupted whilst Silvester's method was resumed for short periods. Strychnine, digitalin, and ether were injected hypodermically to assist the heart which was now showing a tendency to flag. The skull was trephined in two places and the temporo-sphenoidal lobe and cerebellum on the affected side were explored by Mr. Andrew, but unfortunately with a negative result. The only change noticed was the occurrence from five to ten minutes after the completion of the operation of slow lateral rolling movements of the eyeballs similar to those noted by Ferrier as resulting from cerebellar stimulation but also frequently observable during light anæsthesia apart from any head condition. Strong corneal reflex could occasionally be elicited but the pupils remained equal, firmly contracted and fixed, absolute unconsciousness continued, and respiration would not begin. Cardiac action failed considerably, the radial pulse being at times almost imperceptible. It is possible, indeed, that cardiac action at this period was maintained by the intrinsic cardiac ganglia, the higher centres being involved along with the respiratory centres in the medulla oblongata. So strongly had I been impressed by the probable intracranial source of the trouble that up to this time the employment of a battery had not been given a thought. An induction apparatus not being immediately available a 20-cell galvanic battery was obtained, the negative electrode (a small one) being applied to the neck over the region of the phrenic nerve and the positive to the lower intercostal spaces to try to influence the diaphragm. For a minute or two nothing occurred, the negative pole being in all probability inaccurately applied. At this stage, however, we seemed to hit the phrenic nerve and with each re-application of the electrode a distinct spasmodic inspiratory movement took place, accompanied by dilatation of the pupils and a facial grimace, the whole appearance suggesting the final gasps frequently observed immediately preceding death. The arms at the same time became rigid, interfering with the free performance of artificial respiration. After three or four induced inspirations spontaneous respiration began, the patient almost immediately becoming sufficiently conscious to attempt to resist the application of the dressings and the closure of the tracheotomy wound. On the next morning the patient's condition was fairly satisfactory, but 30 hours afterwards, without apparent cause, though after one or two minutes' warning, a similar respiratory spasm occurred, followed by a similar respiratory failure. Treatment, including the use of the faradic current, was maintained for two hours, when death occurred.

Necropsy.—At the post-mortem examination a small collection of pus surrounded by sloughing tissue was found at the anterior portion of the cerebellum.

Looked at from the point of view of the anæsthetist the following points of interest suggest themselves to me.

1. *The anæsthetic.*—Being informed by the nurse in attendance in the anæsthetic room that the patient was a "mastoid case," and as he was quite conscious and presented nothing to attract special attention, I was unaware that any suspicion had been entertained by the surgeon of the probable presence of an intracranial abscess. Otherwise I would have given chloroform in accordance with the advice of authorities on this subject. At the same time the A.C.E. mixture is in my experience in the great majority of cases associated with less excitement and holding of the breath during the period of induction of anæsthesia than is the case with chloroform even when slowly and carefully administered. On this occasion there were practically none of these objectionable effects produced and this, I think, would counteract so far as increased intracranial pressure was concerned any harmful effect caused by its mildly stimulating action on the pulse and respiration. That very little was required to turn the balance was demonstrated by the sequel, for which no distinct exciting cause could be found. On this occasion I understand that the patient, feeling some warning of impending trouble, called his nurse and that when the house surgeon who was immediately sent for saw him there was clearly a spasmodic closure of the upper air passages, evidenced by the presence of lividity and the forcing of air through the previously closed tracheotomy wound. The immediate re-opening of the latter was followed by breathing for a few minutes before the final cessation took place. This would seem to corroborate my opinion that in the first attack, though at first sight the patient seemed to be "coming out," he was not really so, but, as was indicated by the other guides, he was in the stage of light surgical anæsthesia. The respiratory spasm and the spasmodic closure of the jaws (masseteric spasm frequently observed in cerebellar cases) formed the introductory phenomena produced by the intracranial pressure. Whatever part the anæsthetic played in the production of the condition it alone certainly could not account for its maintenance. Possible alterations in the relations of the abscess the result of the somewhat free movement of the patient after he was anæsthetised may also have to be considered in deciding the exciting cause. The abscess from its anatomical position could not possibly exert any direct pressure on the vital centres.

2. *Oxygen* has in my experience proved itself a most valuable remedial agent in serious anæsthetic difficulties and clearly so in this case. Without it after the first half hour the circulation was so feeble and sluggish as even with satisfactorily performed artificial respiration to allow of the onset of dangerous lividity, whilst with Howard's method, so valuable to the surgeon, it was even more necessary.

3. *The recovery.*—In light of the negative result of the exploratory operation and previously to the post-mortem examination one could not but ascribe the credit of the recovery to the use of the battery. With the intermittent application of the electrode over the phrenic nerve not only was there a consequent diaphragmatic inspiration, but the clearly evident action of the ribs and facial grimace resembled more a complete inspiration or gasp, as if resulting as much from the general shock of the application as from the local action on the phrenic nerve. Unfortunately, in the fatal attack this did not occur, so that we must look for another element in the recovery. This I think was the diminished intracranial pressure caused by the gradual drainage of the cerebro-spinal fluid through the trephine openings. The closure of the latter seems to have allowed re-accumulation of the fluid, recurrence of the pressure, and

---

[1] Case of Cerebellar Abscess, by J. Grant Andrew, M.B. Glasg., Brit. Med. Jour., May 2nd, 1903.

a second attack during which their re-opening and tapping might have allowed once more a temporary recovery.

Somewhat similar cases, though mentioned by Macewen, Hewitt, and others, being comparatively rare, the total duration of the respiratory failure being exactly one and a quarter hours, I may be pardoned the above details; and this case is, I think, unique in that recovery, temporary at least, took place without the actual evacuation of the abscess. To what extent this happy result may be ascribed to the battery it is difficult to say, but it cannot be wholly dissociated from it, and faradism certainly now holds, in my estimation, a higher place as a remedial agent in anæsthetic difficulties than it had previously done as a result of my reading on the subject.

Glasgow.

NOTE UPON THE USE OF PILOCARPINE IN THE TREATMENT OF PNEUMONIA.

BY E. CURTIN, M.D.R.U.I.

THE pharmacological action of pilocarpine is well known and its striking action as a diaphoretic has led to its use in many conditions where morbid fluid accumulations have to be removed from the system. It does not appear, however, that its therapeutic value has been tested in pneumonia save by few observers. Thus recently[1] Pelzl records his experiences in an Austrian military hospital where he gave 0·0125 gramme (equal to one-fifth of a grain in solution) of pilocarpine hydrochloride by the mouth with good results. In the same article several theories are given of the action of pilocarpine in cases of pneumonia. In the South African war during 1901–02 I made use of the drug in several cases under my care. The notes of some of these cases are given below. The administration was by means of hypodermic injections of one-tenth of a grain of pilocarpine nitrate in solution of tabloids of that strength. I might draw attention to the fact that the disease in coloured races (I speak especially of Kaffirs in these notes) exhibits some differences from that seen in Europeans—e.g., British troops serving in South Africa. In the latter there is more of the toxæmic character than in the former. The high mortality—no less than from 50 to 60 per cent.—in cases of pneumonia occurring in the coloured races of South Africa has been frequently remarked upon.

CASE 1.—A half-caste scout was admitted to hospital complaining of "stick in the side." The whole of his right lung was dull to percussion and his general symptoms pointed to a severe attack of pneumonia. Repeated cold baths failed to affect his temperature which registered 105·4 F. He passed a restless and delirious night and on the following morning, his temperature having risen to 106°, I gave a hypodermic injection of one-tenth of a grain of pilocarpine. Considerable sweating followed and although there was no immediate reduction [illegible] was much relieved. [illegible] the ensuing night he [illegible] bloody mucus and w[illegible] third day of his illness his temperature was normal and his lung had almost completely cleared. Two days subsequently he left the hospital tent at his own request.

CASES 2 and 3.—Soon after this I had occasion to visit Upington where Dr. Phillips showed me two cases of pneumonia in half-castes. In the first case both lungs were affected and th[illegible]onchial secretions whic[illegible]trength to expel by cou[illegible] of distress that Dr. [illegible]as quite hopeless. The [illegible]ent was one of average severity. Both cases were in the same ward and under similar conditions and were injected with one-tenth of a grain of pilocarpine. Their recoveries were rapid and satisfactory.

A transfer to No. 3 Stationary Hospital, De Aar, from Kenhardt, where there was a native ward equipped with competent attendants, afforded me an opportunity of further testing the value of the drug in pneumonia with the result of a decrease in the mortality in native cases of at least 50 per cent.

In the few cases in which I had an opportunity of applying this treatment to Europeans the results were not so satisfactory as in natives. This I attribute, as already stated, to the toxæmic symptoms which were such a marked feature in soldiers affected with pneumonia during active service in South Africa.

CASE 4.—A private, aged 41 years, with the usual soldier's history, was admitted to hospital suffering from pneumonia of the left lower lobe. The temperature on the morning of admission was 104° F., the pulse was 125, thready and compressible, and the respirations were 50, shallow, very painful, and accompanied by working of the nostrils. His appearance was one of great distress. On the second day after his admission his evening temperature was 103°, but his general symptoms continuing severe I gave one-tenth of a grain of pilocarpine hypodermically with the result of almost immediate arrest of pleuritic pain and relief of general distress. During the ensuing night he expectorated freely. The following morning his temperature had fallen to 100° and redux crepitations had replaced the tubular breathing of the previous day. From the fifth to the ninth day his temperature remained below 100° F. and in every respect he was making satisfactory progress. He then had a rigor which was followed by pneumonia of the right lower lobe. He was again injected with pilocarpine and after a prolonged convalescence returned to duty. The usual stimulating treatment was also employed.

CASE 5.—This patient was a private who was admitted in the evening. There was a patch of dulness of about the size of the palm of the hand over the lower anterior border of the right lung. The morning after admission his temperature registered 103·4° F. and in the evening slightly above 104°. His general symptoms were not severe and he was comparatively free from pain. At 2 P.M. on the second day after admission to hospital I injected one-tenth of a grain of pilocarpine which produced moderate perspiration but otherwise had no immediate marked effect. In the evening his temperature went up 1° to 104°. On the following morning it had fallen to normal, where it remained. He returned to duty on the fourteenth day after his admission and would have been fit sooner but for his indiscretion in having attended a concert.

CASE 6.—The patient, a private, was admitted suffering from pneumonia of the left base. On the following day acute delirium set in with symptoms of profound toxæmia. An injection of one-tenth of a grain temporarily relieved his breathing. On the evening of the third day his temperature, which from the first had been under 102° F., rose to 105°. The injection was repeated, with the result of a reduction to 103° but without relief to other symptoms, especially delirium which continued active until his death at midnight. [illegible] were also used. Notable features [illegible] scanty expectoration, compar[illegible] a few hours before death, and delirium.

CASE 7.—The patient, a private, was admitted complaining of cough and pain in his chest. His temperature was 102 4° F., the respirations were 30, and the pulse was 120. The lower lobe of the left lung was dull to percussion and the breathing was tubular. The right lower lobe was also dull. There was a short sharp cough, with scanty blood-stained expectoration. On the following day dulness on the left side extended to within three inches of the apex. The respirations and pulse were very frequent and the heart sounds were feeble. From this time cough and expectoration ceased and active delirium set in. On the third day after admission subcrepitant râles replaced the tubular breathing of the previous evening. Dyspnœa and cyanosis being marked one-tenth of a grain of pilocarpine was given with the view of liquefying and causing absorption of inflammatory products. On the following morning both lungs had cleared remark[illegible] however, continued and [illegible] Toxæmic features [illegible]so and it resembled the pneumonia seen in alcoholics, as after the first 48 hours there was scarcely any cough or expectoration, the fever was never very high, and there was active delirium. In addition to general stimulating treatment two pints of warm saline [illegible]lar tissue of the axilla. [illegible]btained. A feature in [illegible]

The last two cases are instructive in showing that the prognosis in pneumonia does not depend so much on the extent of lung affected as on the amount of toxic symptoms present and the absence of a healthy reaction in the individual attacked. A low range of temperature is not necessarily a favourable sign, especially if accompanied by delirium, scanty expectoration, little cough, and a dry brown tongue.

---

[1] THE LANCET, March 21st, 1903, p. 823.

From my limited experience of the action of pilocarpine I believe that it will occupy a leading place in the treatment of pneumonia. It relieves pleuritic pain and breathing within a few hours of its administration and also seems to hasten resolution, probably by exciting glandular secretion. Its administration is in the majority of cases followed by a rise of temperature of from half a degree to one and a half degrees. One-tenth of a grain hypodermically does not cause profuse perspiration but rarely fails to reduce the temperature within an hour or two. It also cleans the tongue and stimulates the flow of saliva. I have not noticed its repeated administration attended by any undesirable or unpleasant results. One precaution is necessary—namely, to keep the patient warm and especially the feet. I regret that owing to the loss of some notes and temperature charts I have to generalise instead of giving full statistics and details of the cases, but I trust that from the above rough notes—jotted down while on active service in South Africa—I have succeeded in drawing attention to a drug which will frequently prove of practical value in cases of pneumonia.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

METHYLENE BLUE IN THE TREATMENT OF MALIGNANT MALARIAL FEVER.

BY J. M. ATKINSON, M.B. LOND., M.R.C.S. ENG., D.P.H. CANTAB.,

PRINCIPAL CIVIL MEDICAL OFFICER, HONG KONG.

As is well known, quinine has practically no effect on the crescent bodies met with in malignant malarial fever. It is these bodies which, when ingested into the stomach of the mosquito, undergo those changes which terminate in the formation of the germinal rods or sporozoites. These are carried in the body fluid of the mosquito to its salivary glands and are the actual source of infection in man. Hence the importance of finding some drug that will destroy them. I have recently been trying the effect of the internal administration of methylene blue on a Chinese boy, aged 15 years, who was admitted into the Government Civil Hospital on Jan. 24th, 1903, suffering from malignant malarial fever. On examining his blood numbers of crescents were found and as quinine administered for a week had no effect in diminishing these, on Feb. 9th two grains of methylene blue were given thrice daily in the form of a pill. On the 16th, after careful examination, no crescents were to be found in his blood. As the patient was now suffering from gastric disturbance, nausea, vomiting, &c., which I thought might be due to the drug, it was discontinued. The blood was again examined on the 17th and 20th and was found to be free from crescents.

The above is only one case, I admit, but knowing the importance of reporting the effects of any drug which will kill these crescents I send this note.

Hong Kong.

A CASE OF RUPTURED OVARIAN CYST.

BY ALFRED CLARK, F.R.C.S. EDIN.

ON March 14th, 1903, I was called to see a married woman, aged 25 years, who had been suffering from severe abdominal pain and metrorrhagia at about fortnightly intervals for three or four months. She had one child three and a half years old and had never been pregnant since. I found her in bed, blanched, restless, with sighing respiration, a feeble pulse of 130 per minute, and a temperature of 102° F. Her abdomen was slightly distended, acutely tender, and rather dull on percussion. The left iliac region was a little more full than the right and was more resistant on palpation. With a hypodermic injection of one-fiftieth of a grain of strychnia her pulse improved somewhat and I had her removed at once to a private hospital where at 10 P.M. Dr. T. G. S. Hodson administered chloroform and I opened the abdomen with an incision four and a half inches in length, the patient being in the Trendelenburg position. There was a large quantity of blood clot in the abdominal cavity. After removing this I found an ovarian cyst on the left side about as large as an ostrich's egg with a straight rent in its anterior aspect about three inches in length. Venous oozing was still going on from the edges of the rent. The cyst wall was thick and very adherent to the bladder and small intestines. A piece of cyst wall was so intimately adherent to the latter that I had to leave it lest I should tear the bowel. Then I removed the left ovary and examined the right. This had a thin-walled serous cyst as large as an orange, so I removed this also. The operation lasted about 45 minutes as the adhesions made it tedious and the patient was removed to bed in a bad condition and with a very feeble and fluttering pulse, but she rallied after a hypodermic injection of one-fiftieth of a grain of strychnia. She had rather troublesome vomiting of bright-green material for a couple of days and on the second and third days passed some blood-stained mucus from the bowels. Otherwise she made an uninterrupted recovery. I removed the sutures on the fourteenth day and she was discharged a few days later. A fortnight later she called at my house and said she felt better than she had done for a year or more.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

SOUTH WIMBLEDON AND MERTON COTTAGE HOSPITAL.

A CASE OF CÆSAREAN SECTION FOR CONTRACTED PELVIS; RECOVERY OF THE MOTHER AND CHILD.

(Under the care of Dr. MARTIN RANDALL and Dr. A. H. GERRARD.)

IN this case, which was one of full-term pregnancy, the patient was a primipara, aged 21 years. The pains commenced slightly on August 24th, 1902. On the 26th the patient was seen by Dr. A. H. Gerrard when he found the waters broken and the head presenting above the brim. He came to the conclusion that the pelvis was greatly contracted and he asked Dr. M. Randall to see the case with him. The patient was a small woman but not obviously malformed. Her general condition was good. The pains were regular and strong, the membranes were ruptured, and the os was of about the size of a five-shilling piece. The head could be felt freely moveable higher up. The sacral promontory was very large and projecting, the diagonal conjugate being under three inches. The estimate on measuring was two and seven-eighths inches; this would indicate a true conjugate of not much over two and a half inches. As the head appeared on abdominal palpation to be of normal size, the alternative of craniotomy or Cæsarean section was put to the patient and her friends and the latter was chosen. The patient was removed to the hospital. Dr. D. Findlay administered ether and Dr. Gerrard and Dr. T. Brice Poole assisted at the operation. A hypodermic injection of one-twenty-fifth of a grain of strychnine was given and the vagina was washed out with a 1 in 1000 solution of biniodide of mercury.

After opening the abdomen a piece of stout elastic tubing was passed behind the uterus to the cervix. This was rendered very easy by a thick copper wire passed along the bore of the tubing; the wire was removed as soon as the rubber was *in situ.* Gauze sheets having been packed round the uterus this was quickly incised and opened, the child was seized by the back and removed, and the cord was clamped and cut. Bleeding was free for a few seconds and then the ligature was tightened. The incision at its upper end just notched the placenta which was situated at the fundus. The placenta and membranes were stripped off and the inside of the uterus was swabbed out with biniodide of mercury lotion. The uterine incision was sutured in two layers. Fishing gut was used for the deep sutures which were passed only through muscle and submucous tissue, the peritoneum and mucous membrane being excluded. The peritoneum was then sewn together by interrupted stitches of fine silk so as to bury the knots of the deep sutures. The uterus was now well contracted and was returned into the abdomen. A piece of one Fallopian tube was excised between ligatures but Dr. Randall regrets to say that the other tube was only ligatured once. The peritoneal cavity was found to be unsoiled, so the abdominal wound was sewn up by silkworm-gut sutures. The recovery of the mother and child was normal, the baby being suckled and the mother being desirous of getting up on the third day.

Remarks by Dr. RANDALL.—I must express my thanks to Dr. Gerrard for his skilful after-treatment of the case and for the opportunity of operating on the patient. The only points to which I would draw attention are the ease with which the wire allows the elastic tube to be passed round the uterus—the idea is not original—and the unorthodox, but successful, method of suturing the uterus.

BRISTOL GENERAL HOSPITAL.

A CASE OF TUBERCULOUS PERICARDITIS NECESSITATING FREQUENT ASPIRATIONS.

(Under the care of Dr. J. ODERY SYMES.)

A YOUTH, aged 19 years, was admitted as a surgical patient to the Bristol General Hospital under the care of Mr. C. A. Morton on Jan. 10th, 1903 There was a small superficial abscess in the anterior axillary line over the fourth rib and this was incised and drained. It did not communicate with the pleura, but an exploring needle which apparently was inserted into the right pleural cavity (with great difficulty owing to the falling in of the chest wall) drew off a little pus. Dr. J. Odery Symes saw the patient in consultation with Mr. Morton on Jan. 11th. The pericardium was tapped and five ounces of blood-stained fluid were withdrawn. The boy was transferred to the medical wards under the care of Dr. Symes on the 12th. With regard to the patient's history, he had had no illness of any sort until a fortnight before Christmas, 1902, when he noticed a swelling rise over the front of the right chest. On Christmas Day there were pains in the left chest and back and these had continued since. There was breathlessness on exertion and the patient had to give up work but had not been confined to bed. Cough was slight and no wasting was noticed. On Jan. 12th the condition was as follows. The patient was a delicate-looking, wasted lad. The right side of the chest was flattened and immobile, the lower ribs having fallen in and lying in contact with one another. The left front was unduly prominent, especially over the præcordium. On the right side there were signs of consolidation of the upper lobe of the lung and of fluid in the pleural cavity below. Over the left lung, back and front, the vesicular murmur was harsh, exaggerated, and bronchial and fine râles were heard; the posterior pericardial patch of dulness and the posterior pericardial patch of tubular breathing and ægophony were well marked. The respirations were 38. There was bulging of the præcordial region and dulness extended above as high as the first rib, to the right one inch from the sternal border and to the left to the anterior axillary fold. The heart sounds were almost inaudible and a rough friction sound occurred with respiration in the third left space in front. The pulse was 120, weak, and irregular in force and frequency. The pulsus paradoxus was at times present. The liver was enlarged, being especially prominent in the epigastric region, where, too, it was thought a mass of thickened omentum could be felt. There were fluid in the peritoneal cavity and a trace of albumin in the urine. In consequence of the re-accumulation of fluid in the pericardium tappings were made on the following dates: on Jan. 16th, six and a half ounces were drawn off; on the 31st, five and a half ounces; on Feb. 13th, seven ounces; and on the 20th, 12 ounces. The spot chosen for the punctures was the fourth left costal interspace close to the edge of the sternum. The fluid was blood-stained, the specific gravity was from 1020 to 1024, it was alkaline, cloudy, and when centrifugalised showed in addition to leucocytes a large number of tubercle bacilli. After each aspiration there yet remained a considerable quantity of fluid in the pericardium and for this reason it would have been better to have attacked the sac by puncture up through the epigastrium and this might have been done with a cannula and trocar as the fluid was under positive pressure. The cardiac failure and dyspnœa were much relieved after each aspiration. The progress of the case does not call for much comment. An unsuccessful attempt was made to draw off the fluid from the right base by means of an aspirator but the space between the ribs did not permit of a needle being passed. The friends refused to have any operation performed necessitating the administration of an anæsthetic. Considerable œdema of the right leg and thigh developed and to a lesser degree the left limb was similarly affected. Brief intervals of delirium were noted and for a few days there were symptoms of an abscess pointing at the base of the right lung in front. The red œdematous swelling, however, subsequently subsided. The temperature was of a hectic type throughout. The urine was scanty and albuminous. The patient's strength gradually failed and he died on March 3rd. The friends refused permission to make a post-mortem examination.

Remarks by Dr. SYMES.—The case was apparently one of primary tuberculosis of the right lung, secondary empyema and collapse of the lung, and tuberculous invasion of the pericardium and peritoneum. It is remarkable that the patient was apparently but little inconvenienced by the pulmonary collapse, which from the condition of the chest wall on admission must have been of old standing. He could give no history of a previous illness and had not been incapacitated from work. The pericardial effusion which [illegible] though [illegible] n walk- [illegible] ould be demonstrated in stained films of the exudate is a striking testimony to the value of the electrical centrifuge as an aid to bacteriological examinations. I have to thank the house physician, Dr. C. C. Shaw, for the notes on the case and for performing the required aspirations.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Differentiation of the Continued and Remittent Fevers of the Tropics by the Blood Changes.

A MEETING of this society was held on May 12th, Mr. ALFRED WILLETT, the President, being in the chair.

Sir DYCE DUCKWORTH, who had represented the society at the International Congress of Medicine in Madrid, gave a short account of the work of the Congress.

Captain LEONARD ROGERS, I.M.S., M.D., read a paper [illegible] Continued and Remittent Fevers [illegible] Changes. The paper dealt with [illegible] f continued and remittent fevers worked out during the last two years in the European and native hospitals in Calcutta with both the serum tests and the differential leucocyte count. The question was discussed as to whether there were any hitherto undifferentiated fevers to be met with, such as were described by Dr. Crombie in his address before the Indian Medical Congress in 1894, which had not previously been put to the test of modern methods of diagnosis. In all the cases the differential leucocyte count had been carried out, as Captain Rogers had shown that by its means very valuable aid could be obtained in differentiating typhoid from malarial remittent fevers, this being of the greatest value in this research on account of the impossibility of finding parasites in most cases of malarial fevers which had been given quinine before they came under observation, as was nearly always the case with European patients. 50 consecutive cases of typhoid fever were first dealt with; a short clinical account based on the analysis of the notes and tables of the results of the serum test and the leucocyte counts were given. The latter bore out Captain Rogers's earlier results in a different and smaller series of cases with regard to the very frequent presence of an increase in the percentage of the lymphocytes in typhoid fever without any increase of the large mononuclear white corpuscles, except during the stages of convalescence or in cases complicated by malaria. The frequency of typhoid fever in natives, as shown by the serum test, was then briefly dealt with, and this confirmed Captain Rogers's former experience on this subject—a point of some importance in view of Dr. Crombie's statements that the disease was very rare in natives of India. In a similar way a series of malarial remittent fevers were dealt with and the great value of the large mononuclear increase in the diagnosis of this class of fevers was illustrated. Further certain clinical features of considerable diagnostic importance based on the records of both series of cases were pointed out, which enabled many cases to be accurately diagnosed without the use of the blood tests. Next, the question of the presence of new fevers, in addition to typhoid fever and malaria, was discussed in relation to Dr. Crombie's classification based on clinical experience, and a chart was given of the cases treated in the European General Hospital during the last three years, showing the seasonal distribution of the different forms of fever, which supported the conclusion of Captain Rogers that there were no new fevers of common occurrence and that the so-called "simple continued fevers" were malarial in nature, while that described by Dr. Crombie under the term "non-malarial remittent" and seen by him nearly exclusively in natives was nothing but typhoid fever. Lastly, some recent observations on the so-called "low fever" were recorded and the nature of this affection was discussed. A series of charts illustrating cases of special interest were shown.

Dr. Patrick Manson said that he differed entirely from the conclusions arrived at by Captain Rogers, which seemed to him to be based on quite inadequate grounds. Dr. Manson pointed out that an increase of the large mononuclear leucocytes occurred not only in malaria but was present also in trypanosomiasis and that the diagnosis of malaria could not rest on that point alone. Captain Rogers's experience was founded on observations of fevers seen in Calcutta and could not be applied to tropical fevers generally, since the type of African fevers differed greatly from the fevers occurring in India. He was certain that there were many varieties of continued fever which were neither malarial nor typhoid. He thought that quinine given by the mouth and absorbed was as effectual as quinine given by hypodermic injection. He considered that Captain Rogers's conclusions were premature and not gathered from a sufficiently large field to justify the statements made.

Dr. A. E. Wright said that he neither approved of the conclusions arrived at by Captain Rogers nor of the method on which those conclusions were based. He pointed out that the large mononuclear cell might be very considerably altered by the pressure of the cover-slip and that it was extremely difficult to fix a definite standard of size. He would like to know what the condition of the blood might be and whether there was an increase of large mononuclear cells in the case of a normal man who was taking large doses of quinine. He pointed out that the greatest number of mononuclear cells was not found in those cases in which the malaria parasite could be demonstrated to be present. He was of the opinion that there were many remittent fevers which had not yet been classified.

Dr. George Low agreed that the increase of the mononuclear leucocytes could not be taken as evidence of malaria but he did not think that there was much difficulty in estimating the number.

Captain Rogers replied.

MEDICAL SOCIETY OF LONDON.

Annual General Meeting.—The Pathology and Treatment of Enlarged Prostate.—Chorea in Pregnancy.—Election of Officers and Council.

The annual general meeting of this society was held on May 11th, Dr. Frederick S. Palmer, one of the Vice-Presidents, being in the chair. The annual reports of the council, the honorary librarian, and the house and finance committees were received and adopted.

An ordinary meeting was then held, Mr. A. Pearce Gould, the President, being in the chair.

Mr. W. Bruce Clarke read a paper entitled "Some Points in the Pathology and Treatment of Enlarged Prostate." Reference was made to a paper by Sir William Thomson[1] on the subject, and preference was expressed for the term "prostatic obstruction" rather than "prostatic enlargement," because in many cases where symptoms arose very little enlargement of the gland was present. Mr. Bruce Clarke contended that prostatic obstruction was the result of several pathological conditions and not of one. Some of these were accompanied by enlargement of the prostate and some were not. After quoting various authorities on this point he described three principal varieties of obstruction—(1) adenoma, (2) fibrous prostate due to sclerosis of gland tissue, and (3) varicosity of the veins of the prostatic urethra and trigone. Each of these demanded different treatment. The adenoma must be shelled out, while for the fibrous prostate, which was very difficult to remove, it was quite sufficient to remove one-half of the gland. This plan of treatment had been very successful in his hands. In the vascular prostate the cause of the obstruction was the blocking of the urethral orifice by the prolapse of the mucous membrane of the trigone which was loosened by the subjacent varicose vessels. A method of cauterisation similar to that which was practised in prolapse of the rectum produced satisfactory results. 33 cases were then related, three of which ended fatally, giving a mortality of 9 per cent.—Mr. Reginald Harrison referred to that form of prostatic obstruction due to carcinoma. He related two cases which he had recently observed and exhibited the prostate glands which had been removed. These and other cases showed how impossible it was to eradicate malignant disease from this situation. The high-frequency current and Roentgen rays were probably preferable as a means of treatment.—Mr. F. Swinford Edwards indorsed the previous speaker's remarks as to the comparative frequency of malignant disease as a cause of prostatic obstruction. Several cases in Mr. Edwards's experience had been due to calculus. In cases of soft vascular prostate double vasectomy was advisable. The cystoscope could be employed in most cases of enlarged prostate and its use should not be omitted. The results of enucleation were admirable when the operation did not terminate fatally, and it was often very successful. The hæmorrhage was only moderate in Mr. Edwards's experience.—Mr. Cuthbert S. Wallace denied that there was in the prostate gland a separate capsule in the same sense that the kidney had a capsule. He submitted that total prostatectomy consisted in reality in the shelling out of large adenomatous masses. In regard to vasectomy it had no effect on the prostate. This had been shown by John Hunter.—Mr. Bruce Clarke, in replying, said that his remarks had reference only to non-malignant cases and he admitted that malignant disease was a common cause.

Dr. Cecil Wall and Dr. H. Russell Andrews made a communication on Chorea in Pregnancy which comprised an analysis of 40 cases occurring in 37 patients. The chorea had occurred in the first pregnancy in 18 cases; in 10 cases the first pregnancy was not attended with chorea but the disease occurred in later pregnancies; in six cases chorea had recurred in subsequent pregnancies. 16 out of the 37 patients had previously suffered from rheumatism in some form. In 11 there were no rheumatic manifestations. As regarded the month of pregnancy in which the movements began the largest number of cases were to be found in the fourth and fifth months. There were two spontaneous abortions, and both of these cases were fatal. There were five fatal cases among the 40. In two of these five abortion was induced and in two others abortion had been spontaneous. The use of bromides or opium was strongly deprecated and arsenic was advocated. Induction of premature labour was not recommended.—Dr. Robert Jones said that his experience was limited to cases of chorea associated with insanity, and he dwelt on the association of mental states with muscular movements. Muscular movements were more often associated with dementia and melancholia.—Dr. F. J. McCann remarked that the movements of a fœtus were of a choreic type. There were many different kinds of chorea. The influence of "quickening" on the determination of an attack of chorea was also referred to. Chloral was advocated for its treatment.—Dr. G. E. Herman remarked that the frequency of spontaneous abortion in pregnancy complicated by chorea was not any greater than in normal pregnancies. He did not advocate the induction of premature labour; it certainly did not cure the disease or improve the prognosis in his experience.—Dr. Amand J. M. Routh remarked that two types of chorea were met with in pregnancy, a severe and a mild type. *Chloroform inhalation was efficient in some cases. As regarded the induction of premature labour,* there was great danger of sepsis in these cases when labour was induced, and from this the patient might die; apart from this danger his belief was that it relieved the chorea; though it was not always advisable by any means, it might be indicated in some cases. —Dr. WALL and Dr. ANDREWS replied, pointing out that the records of such cases showed that when abortion was performed the chorea disappeared in a few weeks, but it was a dangerous method to adopt.

---

[1] Brit. Med. Jour., May 31st, 1902.

The report of the scrutineers of the ballot showed that the following gentlemen had been appointed officers and members of the council for the ensuing year:—President, Dr. F. de Havilland Hall. Vice-Presidents: Dr. Frederick S. Palmer, Mr. Henry Morris, Dr. Charles E Beevor, and Mr. Bernard Pitts. Treasurer: Mr. David H. Goodsall. Librarian: Dr. Arthur Francis Voelcker. Honorary Secretaries: Dr. Henry A. Caley and Mr. H. J. Waring. Honorary Secretary for foreign correspondence: Dr. H. D. Rolleston. Council: Mr. Arthur E. Barker, Dr. J. Vincent Bell, Dr. J. Rose Bradford, Dr. J. Walter Carr, Dr. Charles W. Chapman, Mr. F. Richardson Cross, Mr. Frederic Durham, Mr. Frederic S. Eve, Dr. William Ewart, Dr. Robert A. Gibbons, Mr. A. Pearce Gould, Dr. Montague Handfield-Jones, Mr. Jonathan Hutchinson, junior, Mr. Richard Lake, Dr. Marmaduke Prickett, Dr. Arthur H. Robinson, Mr. A. Mayo Robson, Dr. George C. Steele-Perkins, Dr. William J Tyson, and Mr Cuthbert S. Wallace.

CLINICAL SOCIETY OF LONDON.

Hair-ball in the Stomach.—Spinal Meningo-myelocele.—Angioma of Synovial Membrane and Muscle.—Cellulitis of the Round Ligament and Spermatic Cord and its Relation to Strangulated Hernia.

A MEETING of this society was held on May 8th, Mr. HOWARD MARSH, the President, being in the chair.

Mr. C. A. MORTON (Bristol) read a paper on a case of Hair-ball removed from the Stomach. The patient, a young woman, aged 18 years, had a large, hard, and very freely moveable and resonant abdominal swelling which had been noticed for some months. The chief symptoms had been pain and vomiting. The latter occurred mostly after food, but often in the night. No exact diagnosis was possible but the free mobility and resonance suggested an omental mass of tubercle or new growth. The hair-ball weighed 1 pound 12 ounces and measured 6 inches across and was 2½ inches thick. It was removed through a four-inch incision in the stomach and the patient made a good recovery. After operation a history of eating hair and cotton was obtained. References were made to other published cases in which hair-balls had simulated omental growths or fæcal masses in the colon or cystic disease of the spleen and attention was called to the free mobility of abdominal swellings due to hair-balls in the stomach.—Mr. E. P. PATON referred to a similar case under his own care in a child aged nine [illegible] in perfect health, the tumour having

[illegible] notes of a case of Spinal Meningo-myelocele in which *the tumour simulated an abdominal cyst.* He showed the specimen, which was removed from a female child, 11 months old, who displayed various malformations and the abdomen was fuller than natural on the right side, having markedly increased in size during the previous two months. *There was no prominence of the* umbilicus but there was evidently an encysted collection of fluid which, however, did not become tense unless the child strained. Abdominal section was performed and a bluish cyst presented which was tapped, giving vent to about *a pint of clear fluid. The sac was firmly adherent* to the right side of the spine just below the transverse mesocolon. The finger could be passed through it into a hole in the side of the spinal column. It was ligatured and cut away. There was no appearance of nerve structures in the cyst wall. The *fluid had a specific gravity of 1002* and was alkaline, being obviously of cerebro-spinal origin. The child died ten days later. Post mortem extensive abnormalities of the spinal column were found, the defect involving the bony walls of the right side of the last two dorsal vertebræ and *all the lumbar region. The development of the bodies of the* vertebræ was very irregular. There was marked dilatation of the central canal of the cord. With this specimen he showed one from the museum of the Royal College of Surgeons of England (No. 322), exhibiting a similar defect of the vertebræ.—Mr. R. CLEMENT LUCAS remarked that on examining the specimen there appeared to be an absence of the lateral portions of the vertebræ and laminæ on the right side, suggesting that there might have been a projection behind, the fluctuation *of which would have been* communicated to the intra abdominal tumour. He asked whether the brain had been examined and whether any obstruction in the fourth ventricle was noted.—Mr. ROBINSON, in reply, said that there was no projection posteriorly. The brain was examined but no abnormality was noted.

Mr. F. S. EVE read a paper on four cases of Angioma of Synovial Membrane and of Muscle. Case 1 was that of a girl, aged 15 years, who had a swelling on the outer side of the thigh just above the knee, of four years' duration, which was gradually increasing. An exploratory incision was made. The swelling was found to be a diffuse angioma involving the upper part of the synovial membrane of the knee and the vastus externus muscle. It was removed with the affected portion of synovial membrane. A good recovery resulted. Case 2 was that of a boy, aged 10 years, who had a painful swelling which restricted movement occupying the left knee-joint and the inner side of the ligamentum patellæ, causing pain and loss of mobility. A transverse incision was made into the joint and a rounded angioma of synovial membrane, about three-quarters of an inch in diameter, was removed. Case 3 was that of a woman, aged 23 years, who had a painful swelling on the inner side of the elbow which rendered movement difficult. An angioma of [illegible] nal condyle and the [illegible] t of a man, aged 24 [illegible] posterior aspect of [illegible] '-looking growth was removed from the triceps, anconeus, and synovial membrane, which was found to be an angioma. All the cases occurred between the ages of 10 and 25 years. Some of the patients complained of symptoms suggestive of tuberculosis such as pain *increased by movement, and tenderness* and limitation of movement; two showed wasting of muscle and two had "starting" pains. In Cases 2 and 3 the angioma was entirely confined to the synovial membrane. The swelling was usually soft and elastic but pulsation and the emptying of it by pressure were *not observed. No record* of cases of angioma of synovial membrane could be found, but Campbell de Morgan in 1864 and others since had described cases of angioma of muscle.—The PRESIDENT [illegible] cases of precisely the same kind [illegible] *He suggested that the* [illegible] umed and so came to present a close resemblance to active tuberculous disease. He referred to a case at St. Bartholomew's Hospital in which the patient presented a pulsating tumour in the thigh which was thought to be an aneurysm and *was sent in for ligature.* On examination the pulsation was found to be very variable and under an anæsthetic the tumour entirely disappeared. It was probably a cavernous angioma of muscle.—Mr. CLEMENT LUCAS observed that most surgeons were familiar with this condition as met with *in muscle and he referred to* one case in which a very extensive nævoid condition reached *from the thigh a long distance down the leg in a girl.* It took several operations for its complete removal and the synovial membrane was in this case also extensively involved. He urged that in view of *the success of surgical intervention* they should not be afraid to operate in such cases.—Mr. PATON *showed a specimen from a woman, aged 20 years.* She had had an elongated soft swelling on the inner side of the thigh for several years which had increased consequent upon cycling. *The skin over it was normal and on* pressure it could be made almost to disappear. There was neither pulsation nor thrill. It involved, and was limited to, the gracilis muscle in its entirety and the muscle was excised from end to end. He called attention to the size of the vascular spaces.—Mr. ROBINSON recalled a case in which the flexor muscles of the forearm were involved without the skin being affected.—Mr. H. W. PAGE related the case of a man, aged 23 years, who was admitted to St. Mary's Hospital with a markedly pulsating swelling of three or four weeks' *standing in front of the right knee;* it was associated with much pain and rendered him unable to work. The diagnosis was very obscure. The swelling proved to involve the whole of the bursa beneath the patellar ligament and much of the synovial membrane as well as muscle. The magnitude of the operation which the complete removal would have entailed led him to think that amputation of the limb would have been the only course. He was surprised to find that these cases were not so rare as he had believed.—Mr. EVE, in reply, agreed that symptoms might sometimes be due to temporary congestion as in Case 2, but he had never seen any trace of acute inflammation. He said that angioma of muscle alone was not rare and what he wished to point out was that the lesion might involve synovial membranes as well as muscles. In one of his cases the tumour had undergone almost entire metamorphosis into fat.

Mr. E. M. CORNER read a paper on Cellulitis of the Round Ligament and the Spermatic Cord and its relation to Strangulated Hernia. The first case was that of a young married woman who had been confined a year previously. Five days before admission her attention had been drawn to a lump in the left groin which caused pain. The lump increased in size and she vomited irregularly. The case was diagnosed as one of strangulated inguinal epiplocele with perhaps also a partial enterocele. At the operation the end of the round ligament with a lymphatic gland on it was found to be inflamed. The ligament was ligatured above this and the diseased part was removed. Leichtenstein and Hermann had recorded a similar case. From consideration of these two cases it was suggested that the mischief arose in an unhealthy condition of the endometrium following delivery, with consequent lymphadenitis of the gland alongside the distal end of the round ligament which was secondarily affected with cellulitis. This gland was known to be occasionally enlarged in cases of carcinoma of the fundus uteri. A case of cellulitis of the spermatic cord was also related, which occurred in a man, aged 25 years, as the result of a kick. The tumour was accompanied by vomiting and constipation of the bowels. Under treatment with hot lead lotion the swelling subsided. Three years later the testicle on that side was softer and much smaller than the other. These two processes illustrated in woman and in man respectively the fact that cellulitis of the round ligament and the spermatic cord might complicate the diagnosis of strangulated hernia.

OBSTETRICAL SOCIETY OF LONDON.

The Anatomy of the Pregnant Tube.—Exhibition of Specimens —Inversion of the Uterus.

A MEETING of this society was held on May 6th, Dr. EDWARD MALINS, the President, being in the chair.

Dr. H. RUSSELL ANDREWS read a paper on the Anatomy of the Pregnant Tube. He discussed the reasons why accurate knowledge of the minute anatomy of the pregnant tube had been only recently acquired. From a study of the literature of the subject, chiefly that of the last seven years, and from sections made by himself he gave a short description of the histological appearances of the tube and ovum in early tubal pregnancy. The question of tubal decidua was first discussed. In intra-uterine pregnancy decidual changes were not confined to the corporeal endometrium, similar changes being found in the connective tissue cells of the cervical endometrium and ovaries and also in the peritoneal cells. In tubal pregnancy decidual changes were found in the endometrium and in the connective tissue cells of all parts of the tube. A compact decidua, comparable to that formed in the uterus, was not formed in the tube, the difference in the amount of decidua in the two organs depending on differences in their anatomical structure. Dr. Andrews drew attention to the difference in the structure of the mucous membrane of the tubal folds and that of the mucous membrane between the folds. The latest researches on the imbedding of the ovum in the uterus were briefly mentioned and attention was drawn to the fact that the method of imbedding of the ovum in the tube was at first similar to this normal process, but that later the ovum bored its way into the tubal muscle on account of the comparative thinness of the tubal mucous membrane. The fœtal part of the placenta formed in the tube was in every way identical with that formed in the uterus. The maternal part, however, was markedly different in the two organs. A short account was given of the trophoblast as seen in the tube and it was shown that it was exactly like the trophoblast as described by Peters in uterine pregnancy. The danger to life associated with tubal pregnancy was due to the deep situation of the tubal placenta and the comparatively small amount of decidual formation. Abortion and rupture were explained as being results of the penetrating action of the trophoblast. These two accidents were very similar in etiology, the former being an "internal rupture," caused, as was the latter, by the destructive action of the trophoblast. The breach of surface on either the peritoneal or mucous aspect of the tube was brought about either directly by destruction of tissue by the trophoblasts or indirectly by increase of pressure due to bleeding from vessels the walls of which had been destroyed by these fœtal cells. Dr. Andrews came to the following conclusions :—1. That decidual formation did not occur in the tube in the early months of pregnancy to an extent comparable with that seen in the uterus. In many tubes the formation of a compact layer of decidua was anatomically impossible. 2. That the site of the ovum was outside the lumen in the tubal muscle. It seemed impossible to explain this deep site, except as being due to the eroding action of the trophoblast. 3. That the vessels were opened by the trophoblast. 4. That rupture and abortion were mainly brought about by the destructive action of the trophoblast.—Dr. T. W. EDEN said that Dr. Andrews was to be heartily congratulated upon the interesting and important contribution which he had laid before the society. So many points were raised that criticism of the paper was difficult, but he would like to make one or two remarks upon the mode of implantation of the tubal ovum, as described by Dr. Andrews. On reading what Dr. Andrews had to say upon this point he had been struck with the fact that there was remarkably little direct evidence in support of the contention that the ovum was implanted in the muscular layer of the tubal wall. With the exception of the case described by Füth there was practically no evidence at all in support of it ; possibly the specimen shown to the society that evening by Dr. Cuthbert H. J. Lockyer would confirm Füth's conclusions, but at present it was impossible to speak definitely upon the point. On the other hand, it was to be borne in mind that the French school, as represented by Couvelaire and Cornil, entirely contravened Füth's position ; it seemed to him that Dr. Andrews had not done justice to the important work of Couvelaire. His monograph, "Études *Anatomiques sur les Grossesses Tubaires*," was the most important work on the subject which had appeared since Clarence Webster's "Ectopic Pregnancy," yet Dr. Andrews had not made any mention of it in his paper. Couvelaire's view was that the tubal ovum was never completely imbedded in the tubal wall, as the uterine ovum was in the uterine wall, but remained with its outer pole uncovered except by an adventitious layer of fibrin ; this he called the "free pole" of the ovum and described its relations with great minuteness. This decided difference of opinion upon a question of fact between Füth and Couvelaire appeared at first sight to be very perplexing, but it was possible that the explanation was to be found in the fact that Füth's ovum was much younger than any examined by Couvelaire. Their experience in regard to the uterine ovum had taught them that developmental questions could only be solved by the examination of very early specimens ; deductions drawn from appearances found at later stages were very apt to be erroneous. He therefore welcomed the appearance of Dr. Lockyer's specimen which ought to yield important evidence upon this point. Another matter to which Dr. Eden wished to refer was Dr. Andrews's use of the expression that the tubal ovum developed "outside the lumen of the tube." This appeared to him not in any way to add to the accuracy of their conception of tubal pregnancy. Since Peters had shown that the uterine ovum buried itself in the decidua and developed there, it would be equally accurate to speak of the uterine ovum as developing outside the cavity of the uterus, but no one proposed to do so. He thought the point that Dr. Andrews should try to emphasise was that he regarded tubal implantation as intra-muscular and uterine implantation as intra decidual.—Dr. LOCKYER, in connexion with this subject, showed a case of Incomplete Tubal Abortion which demonstrated the mode of implantation of the ovum in the wall of the tube. The specimen illustrated very clearly one of the most important points of Dr Andrews's paper—viz., that the manner in which the impregnated ovum burrowed by means of its trophoblast through the mucosa and into the muscle of the tube-wall, and there developed outside the lumen, was strictly analogous to what normally took place in the uterus, as proved by Peters's specimen of early uterine pregnancy. Peters showed the fallacy of the older ideas regarding the mode of formation of decidua reflexa in which the ovum was regarded as a passive cell which acquired a covering of *decidua by the latter growing up on all sides to inclose it.* Peters proved that the ovum by means of its trophoblast penetrated the endometrium and Dr. Lockyer's specimen proved that the same process took place in the tube when the impregnated ovum lodged in that structure. The value of this specimen lay in the fact that the "capsularis" of the placenta was complete and this, Dr. Lockyer believed, afforded a hitherto unique observation. It negatived the view of Couvelaire that one pole of the ovum remained uncovered by a capsule derived from the wall of the tube. Couvelaire's researches were carried out on material derived from older specimens of tubal pregnancy than the one exhibited by Dr. Lockyer. In the latter the placenta had a diameter of half a centimetre only and although hæmorrhage had taken place in the placental tissues no blood had escaped into the lumen of the tube; consequently the placental capsule which projected into the lumen was uninjured by mechanical pressure and its microscopical structures were easily demonstrated. The sections were illustrated by colour drawings.—Mr. J. H. TARGETT had examined four cases of very early rupture of a gestation sac in the isthmus or narrowest part of the tube. In one of these cases rupture occurred on the seventeenth day after a single coitus (rape). They all showed extensive destruction of the muscular coat by the phagocytic action of the fœtal epithelium and ultimate rupture of the serous membrane. He had also examined a considerable number of ampullary gestations, most of which were tubal moles, and in none of them was there anything at all comparable with a uterine decidua, either beneath or around the ovum. He doubted whether the muscular coat would be penetrated so early in the ampullary gestation as in that of the isthmus, because in the former situation the ovum had much more *room to expand.—Dr. ANDREWS, in reply, thanked the* Fellows for the way in which they had received the paper. He had not had access to Couvelaire's monograph while writing his paper but had read it since. He did not consider that what might be called the German theory of the formation of the "capsularis" was disproved by Couvelaire's description of the membrane covering the "free pole" of the ovum. He had seen serial sections which proved the presence of muscle in the "capsularis." He quite admitted that in the majority of specimens it was impossible to demonstrate a perfect "capsularis," because the majority of specimens were spoilt by bleeding. He considered Dr. Lockyer's specimen an exceedingly interesting one, as showing a thin layer of muscle between the ovum and the lumen of the tube.

Dr. W. H. B. BROOK (Lincoln) showed a Uterus which he had removed by vaginal hysterectomy for primary tuberculosis of the cervix. A microscopical section from the same specimen, showing typical tuberculous structure with giant cells, was also exhibited. The specimen was removed from a married woman, aged 50 years, whose mother and one brother had died from phthisis. Since December last she had suffered from backache and leucorrhœa. On examination in February a circular ulcer with sharply-cut edges and a ragged depressed surface which did not readily bleed was found. A portion of this being excised showed the presence of multi-nucleated tuberculous giant cells. The whole uterus was removed on April 4th, the tubes and ovaries, which appeared healthy, being left. The body of the uterus was not affected nor was there any evidence of tubercle elsewhere. The patient's husband was a strong healthy man.—The case was discussed by Dr. C. J. CULLINGWORTH and Mr. TARGETT.

Dr. W. W. H. TATE showed two specimens of Fibromyoma of the Cervix treated by Abdominal Hysterectomy; Mr. J. S. FAIRBAIRN exhibited a specimen of a Cervical Fibroid which had given rise to severe hæmorrhage; and Dr. A. L. GALABIN brought forward Three Fibroids of the Cervix removed by hysterectomy.—In the discussion which followed Dr H. R. SPENCER, Dr. CULLINGWORTH, Dr. G. F. BLACKER, Mrs. STANLEY BOYD, and Dr. AMAND J. M. ROUTH took part.

Dr H. WILLIAMSON showed a specimen of Embolism of the Pulmonary Artery occurring 24 days after delivery. Eight days after delivery the uterus was explored on account of symptoms of septic infection and a small piece of retained placenta was removed. The patient made a good recovery and she was discharged from hospital 16 days later. On her way home, however, she suddenly became unconscious and died in a few minutes. At the post-mortem examination a large embolus, completely plugging the pulmonary artery, *was found. The right uterine and internal iliac veins were* also thrombosed.

Mr. STANLEY BOYD read a short communication on an unusual case of Inversion of the Uterus.—Dr. ROUTH and Dr. GALABIN took part in the discussion which followed.

OPHTHALMOLOGICAL SOCIETY.

Exhibition of Instruments, Cases, and Specimens.

A CLINICAL meeting of this society was held on May 7th, Mr. W. LANG, the President, being in the chair.

Captain R. H. ELLIOT, I M S., showed Vafiadi's Instrument for detecting Feigned Amblyopia. This instrument was constructed so that when looked into with both eyes open certain objects could be seen with one eye and certain others with the other eye, but it was practically impossible to say with which eye the objects were seen. If a patient who was supposed to have one blind eye described what he could only see with the two eyes together it proved that both possessed vision.—Remarks were made by Mr. W. M. BEAUMONT Mr. W. A. FROST, and the PRESIDENT.

Mr. G. BROOKSBANK JAMES showed a new Portable Perimeter, the chief feature of which was the small and compact compass in which it could be shut up for travelling purposes. It was made by Messrs. Baker of Holborn.

Mr. G HARTRIDGE showed a woman who had Zonular Opacities in both Corneæ. For ten years there had been gradual failure of vision and posterior synechiæ were present in both eyes. Right vision = fingers; left vision = $\frac{6}{60}$ There was no definite specific history although the eyes were inflamed after the birth of her eighth child.—Both Mr. FROST and the PRESIDENT thought that there were probably other degenerative changes at the back of the eye.—Mr. G. HARTRIDGE proposed to try to remove the opacity by scraping.

Mr. G. W. ROLL showed a boy, aged 17 years, who had Microphthalmos with about 20 dioptres of hypermetropia. There were no colobomata of either iris or choroid and the vision right and left was less than $\frac{6}{60}$; with sph. + 15 D. it was $\frac{6}{36}$ with each eye. He had used atropine once but supplemented it with eserine on account of his fear of producing glaucoma.—Mr. FROST had seen a similar case in which glaucoma had been produced by the use of atropine in a patient aged 40 years.

Mr. PERCY FLEMMING and Mr. J. H. PARSONS exhibited Lantern Slides of an Eye which had all the appearance of containing a Glioma; it proved, however, to be one of persistent hyaloid artery with other congenital peculiarities.

Mr. SYDNEY STEPHENSON showed a man, aged 48 years, who had suffered from Gonorrhœa 15 years ago but denied syphilis. He now had several papillomata along the right eyelids and another on the hard palate. They had been removed several times but had recurred. Microscopic sections were shown, but as Mr. Stephenson had not removed them himself he was unable to say if their bases had been cauterised.

Mr. A. S. MORTON described a case of Conical Cornea in a woman whom he first saw in 1880 when she was aged 32 years. Right vision = J. 1 at two inches and left vision = J. 2 at two inches and less than $\frac{6}{60}$ with both eyes but with correction $\frac{6}{24}$. He excised the apex of the left cone at that time and afterwards did the same to the right. In 1881 the right vision with a low + sph. and cyl. = $\frac{6}{6}$ and J. 1 at a good distance and the left vision $\frac{6}{9}$ and J. 1 with sph. + 2. In February, 1901, the vision with both eyes remained at J. 1 at 12 inches and $\frac{6}{9}$, this being 21 and 22 years after the operations in the respective eyes. The scar was barely visible even with a good illumination. He had operated upon about 25 eyes for this disease and proposed shortly to publish his results; some of these he had done with the cautery.—Mr. FROST said that he preferred to use the cautery.—Mr. S. JOHNSON TAYLOR asked if the piece was always cut vertically.—The PRESIDENT thought that a vast number could be greatly improved with high convex cylinders without operation.—Mr. H. E. JULER thought that Mr. Morton's case was a marvellously good one. He himself preferred to use the cautery and to puncture.—Mr. MORTON, in reply, said that he always excised a vertical portion and one case in which he had used the cautery gave him the greatest anxiety although the patient eventually made a good recovery. When he used this method he much preferred to puncture.

A Contribution to the Study of Rheumatic Iritis.—Two Cases of Tuberculous Choroiditis.—Report of Five Cases of Glaucoma in which Adrenalin caused an Increase of Tension.—Proptosis with Deformity of the Head.

An ordinary meeting was held on May 8th, Mr. LANG, the President, being in the chair.

Dr. A. PAINE and Dr. F. J. POYNTON communicated a paper illustrated by lantern slides in which they endeavoured to establish the identity of the pathological changes in Rheumatic Iritis with those occurring in other accepted rheumatic affections. The diplococcus of rheumatism developing in the tissues and cells rather than in the fluid exudate rendered the identification of micro-organisms in fluids obtained by paracentesis of the anterior chamber unsatisfactory, while the opportunities of examining the iris itself in the acute phase of inflammation in the human subject did not often occur. The specimens, therefore, of iris exhibited, which showed the diplococci *in situ*, had been produced experimentally in rabbits. The distribution of the organisms was similar to that occurring in the synovial membranes, showing dense clumps.—Observations were made by the PRESIDENT, Mr. HARTRIDGE, and Mr. W. T. HOLMES SPICER in regard to the extreme rarity of iritis as a complication of true acute rheumatism and the probability that most cases of so-called rheumatic iritis had really their origin in gonorrhœa.—Dr. POYNTON, in reply, said that the demonstration of the special micro-organisms when present required nothing beyond the ordinary methods of preparation and staining. He was not sanguine about finding them in portions of iris removed in the quiescent period, as the subsidence of active inflammation was dependent on their destruction or reduction to a state of latency.

Mr. W. H. H. JESSOP described two cases of Tuberculous Choroiditis, one associated with Conjunctival Tubercle. The first case, that of a girl, aged nine years, was seen on Oct. 29th, 1901, when complaint was made of a burning sensation in the right eye associated with periodical attacks of inflammation and prominence of the lower lid. Later there developed a smooth, round, non-fluctuating swelling in the outer part of the conjunctiva which nearly reached the limbus of the cornea with enlargement of glands in the neck. In the right eye tension was – 1 and vision was $\frac{6}{60}$. There were two areas of detachment of the retina corresponding with two masses obscuring the disc. The external growth was incised and proved to be tubercle by inoculation experiments, characteristic bacilli being obtained. When seen again on Jan. 30th, 1902, vision was $\frac{6}{18}$; the masses in the fundus had practically disappeared, leaving patches resembling albuminuric retinitis, without either pigment, new vessels, or vitreous opacities. The second case was that of a woman, aged 23 years, who complained of misty vision and of a black spot in the field; the vision was $\frac{6}{18}$. A cyst in the breast was found to contain tubercle bacilli and there was a strong family history of tubercle. While under observation masses in the choroid similar to those described in Case 1 were seen to spread from the centre towards the periphery of the fundus, leaving but little trace behind them, and now after three years and four months the patient had recovered with good vision. Reference was made to 42 cases collected and described by Dr. George Carpenter and Mr. Sydney Stephenson.—Mr. STEPHENSON said that tubercle of the choroid, like some other conditions regarded as rare, ceased to be so when systematically looked for. Among 119 cases of tuberculosis which he had examined in surgical wards he had found 11 instances of affection of the choroid; further investigation had disclosed others but had not disturbed the proportion of about 10 per cent. in which the choroid was involved. He indorsed Mr. Jessop's observation as to the absence of residual pigment and vitreous opacities.—Mr. JULER inquired whether these cases had been treated by subconjunctival injection, as one case was on record in which the patient had recovered under local treatment alone.—Mr. JOHNSON TAYLOR asked if the open-air treatment was of use in such cases and suggested that the appearances described suggested to him congenital syphilis.—Mr. HOLMES SPICER said he had regarded tubercle of the choroid as very rare, whereas syphilitic changes in the choroid were comparatively common, and asked how they could with certainty be distinguished.—Mr. STEPHENSON said that of the cases he had collected 50 per cent. had been confirmed as tubercle, both pathologically and bacteriologically. The history was an important factor in the diagnosis, but in tubercle the lesion was solitary and centrally situated, while in syphilis it was multiple and peripheral in distribution.—Mr. JESSOP insisted on the importance of there being no residual pigmentation; he thought that the combination of tubercle with congenital syphilis was very common. In regard to treatment he had adopted little besides "the air at Margate."

Mr. A. F. MACCALLAN reported five cases of Glaucoma in which Adrenalin caused an Increase of Tension. The subject was of interest in connexion with the extended use of this drug in ophthalmic operations. In Case 1 the patient was a woman who had been treated by free instillation of eserine in both eyes. Tension in the right eye was normal; in the left it was + 1. After the use of adrenalin and eserine together there were headache and vomiting and tension in the left eye was + 3. In Case 2 a man suffering from acute glaucoma had a tension of + 2 in the left eye and + 1 in the right eye. Adrenalin and cocaine were applied before operation and the tension in the right eye rose to + 2. In Case 3 a woman suffering from acute glaucoma in the right eye, after the use of eserine presented a tension of + 1; the addition of two drops of adrenalin solution raised it to + 2. In Case 4 the patient was a man with increased tension who after the use of adrenalin presented symptoms of glaucoma, the tension being raised to + 2. After operation the vision was $\frac{6}{9}$ in each eye. In Case 5 a woman with acute glaucoma improved under eserine, the tension being + 2. Adrenalin was applied before operation with the result that tension was raised to + 3 and hæmorrhage occurred. An increase of tension was not the invariable consequence of the use of adrenalin, but it was common in cases of acute and subacute glaucoma, and in two such retinal hæmorrhage had occurred in the experience of Mr. MacCallan. Other cases in which adrenalin had been used showed no change in tension or in the fundus, but the vascular constriction produced by adrenalin appeared to prevent the absorption of other drugs such as those employed to contract the pupil.—Mr. N. BISHOP HARMAN mentioned the use of adrenalin solution in a case of episcleritis. The vision was reduced to $\frac{6}{36}$ and J. 8 with diminution of the colour fields. Improvement occurred after a week, the patient having discontinued the drug himself on account of the stinging pain which it caused.—Mr. JESSOP spoke of the pain and increased tension produced by the use of adrenalin in scleritis and episcleritis; he found that engorgement followed constriction of the vessels.—Mr. PARSONS thought that the effects of adrenalin in diseases of the eye were by no means uniform. Complications following its use were probably due to dilatation of collateral or deep-seated vessels and reactionary dilatation of the superficial ones after the initial contraction had subsided.—Mr. HOLMES SPICER thought that when the arteries were rigid the drug probably caused contraction of the veins.—Mr. JOHNSON TAYLOR considered adrenalin to be useful in limiting hæmorrhage if not otherwise dangerous; since using it he had observed no hæmorrhage in cataract extractions.

Dr. E. DONALDSON communicated a case of Proptosis and Deformity of the Head in a Male Child, two and a half years old, who was the youngest of three. There was nothing in the family history; the labour had been tedious but at full time and no instruments were used. The proptosis was present at birth to much the same extent as now. Half-a-dozen times the right eye had become dislocated forwards outside the lids. The child was in fair health except for slight rickets, the mother having continued to suckle him up to the present time, and he could walk well. He was 2 feet 8 inches high and there was no defect in other special senses or intelligence. The forehead was prominent in the mid-line and depressed on either side. The margin of the lids only just reached the limbus of the cornea in the primary position; in all movements of the eyes the sclerotic was exposed above and below. There was slight horizontal nystagmus; the eyes could be closed and the corneæ were covered during sleep. Movements were free with a tendency to diverge, particularly in the right eye; there was no pulsation and the globes could not be pressed back. So far as could be made out with the finger there was no deformity of the orbital plate. The anterior fontanelle was closed. The vision was defective, the optic discs being pale, but there were no corneal opacities. The case appeared similar to one shown by Mr. H. Power and recorded in the Transactions of the society, vol. xiv., p. 212, the shallowness of the orbits being due to premature synostosis as pointed out by Mr. H. R. Swanzy in vol. xviii., p. 15

Mr. R. W. Doyne showed a card specimen of Multiple Deformities of the Eye and Eyelids.

LIVERPOOL MEDICAL INSTITUTION.

Intestinal Obstruction caused by Bands—Somnoform—Therapeutic Applications of Chloretone.—Influence of the Semi-circular Canals and Labyrinth upon the Movements of the Eyes and Head.

A MEETING of this society was held on April 30th, Mr. Rushton Parker, the President, being in the chair.

Mr. G. P. Newbolt read notes of two cases of Intestinal Obstruction caused by Bands and successfully operated upon. In one, a woman, aged 31 years, there was a recurrence of the condition six months later, when a second successful operation was done at Damascus. In the other case, that of a woman, aged sixty years, two operations had been already performed for strangulated umbilical hernia and the third obstruction was due to a thick omental band under which a coil of intestine had slipped.—The President mentioned the importance of treating intestinal obstruction by starvation and opium. He quoted a case in which this line of treatment was successful. A recurrence took place and operation was necessary as the symptoms did not yield to treatment.

Mr. F. W. Bailey read a note on Somnoform, describing its composition and alleged advantages Its physiological action on respiration, circulation, and the nervous system was also discussed and a description of the mask and method of administration was given. Mr Bailey alluded to the difficulty of knowing when anæsthesia was complete. In his opinion the development of a full and bounding pulse was the sign most to be relied on. No bad effects, he said, were noticed after single administrations, but after repeated doses he had met with violent headache and in one case there was collapse.—Mr. W. Fingland thought that whatever could be done by somnoform could be better and more safely done with nitrous oxide.—Dr. F. E Marshall said that the chief objections to somnoform were its uncertainty of action and its disagreeable taste. It was easy to carry about He, too, had noticed extreme throbbing headache which came on several hours after administration. He thought Bauer's or Ormsby's ether inhaler preferable to the handkerchief mask usually employed.—Mr. E M Stockdale, Mr. C. H. B. Shears, and the President spoke and Mr. Bailey replied

Dr. D. M. Hutton read a short communication upon Some Therapeutic Applications of Chloretone. He had found the drug of great service in the vomiting of pregnancy, menstrual sickness, and sea-sickness. As a hypnotic and [illegible] stomach he could not [illegible] W. Macfie Campbell, [illegible] Warrington, and Dr. R. W. MacKenna also spoke and Dr. Hutton replied

Dr. Edgar Stevenson read a paper on the Influence of the Semi-circular Canals and Labyrinth upon the Movements of the Eyes and Head. He rapidly reviewed the anatomy and nervous connexions of the canals and alluded to experiments on the subject made by himself and others He suggested that they were the end organs of the seventh sense—that of orientation, and further that muscle tone was maintained by the integrity of the canals. The paper was illustrated by lantern slides and by the gyrations of some Japanese dancing mice.—Dr. K. A. Grossmann said that vertigo was not exclusively due to auricular causes or to a continuation of inertia after movement, for some forms were exclusively ocular—Dr. Warrington, Dr F. A. Gill, and Dr. Edgar A. Browne spoke and Dr. Stevenson replied.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Lipæmia in Diabetes Mellitus.—Clinical and Experimental Observations upon General Paralysis.

THE eighth ordinary meeting of this society was held on May 6th, Sir T. R. Fraser, F.R.S, the President, being in the chair.

Before proceeding to the general business of the evening Sir William Turner, K.C.B, LL.D., Principal of the University of Edinburgh, was elected an honorary member, and Professor Fritz Strassmann of Berlin a corresponding member, of the society.

Dr. D. Chalmers Watson showed a case of Keratosis Pilaris (with photographs to illustrate treatment). Dr. Watson also gave a microscopical demonstration on the histo-pathology of the disease.

Mr. David Wallace, C.M.G., *showed a Patient after* Injection of the Nose with Paraffin (with photographs).

Dr. Norman Walker showed two cases of Lupus Erythematosus.

Dr. W. H Miller exhibited a case of Hypertrophy of the Breasts in a girl.

Mr. H. Alexis Thomson showed a patient after High Excision of the Rectum for Carcinoma with Preservation of the Sphincters and Complete Control.

Mr. Charles W. Cathcart showed (1) a patient after *Kocher's Operation of Gastro-duodenostomy for Pyloric* Obstruction; and (2) a patient after Compound Fracture of the Femur caused by two wheels of a loaded goods wagon passing over the thigh.

Mr. Cathcart also showed a Three-way Stop-cock for use in washing out the stomach or bladder.

Mr. Wallace showed a skiagram of a Dart in the Orbital Cavity.

Mr. A. Miles showed (1) Intestine from a case of Hernia into the Duodeno-jejunal Fossa; and (2) Foreign Bodies *from cases of Ano-rectal Fistulæ*

Dr Watson showed Photographs of a Dog affected with Disease of the Thyroid Gland associated with marked Obesity.

Dr. F. D Boyd, C.M.G, gave a demonstration of Bancroft and Haldane's Apparatus for estimating Oxygen and Carbonic Acid in Small Quantities.

The President communicated a paper on Lipæmia in Diabetes Mellitus. He stated that he had brought the case before the society on account of the interest and rarity of the *disease and because of the complete demonstration that was* obtained post mortem of the existence of a large quantity of fat in the blood as well as of its presence during the life of the patient. The case was that of a youth, aged 17 years, who was admitted to the Edinburgh Royal Infirmary in May, 1902, suffering from the ordinary symptoms of diabetes mellitus The patient had been in comfortable circumstances, was well fed, with no alcoholic tendency, and with a good family history. His work did not unduly expose him, as he usually worked under an open shed. *He had enjoyed* good health *until* 12 weeks *previous* to his admission, when he began to complain of great thirst, polyuria, and loss of weight. He was then seen by Dr. J. Macdonald of Carlisle who put him on a strict diet, together with morphine and under this treatment his condition improved somewhat. On admission the patient exhibited a fair amount of muscularity; his temperature was subnormal and remained so during the whole course of his illness. His breath had the acetone odour; the appetite was not voracious; the bowels were regular and occasionally moved twice in the day; the motions were well formed and of a good colour. There was no tenderness over the abdomen or pancreas and the liver and spleen were of normal size The respiratory and circulatory systems were healthy, the pulse was slow and of low tension, there was no evidence of neuritis, and the fundus oculi was normal. As regards the urine, glucose, acetone, and diacetic acid were present. On admission he was placed on ordinary diet for some days, from May 19th to June 3rd. On June 4th diabetic diet was commenced and on the 20th 20 grains of phosphate of sodium were given twice daily and this really constituted the whole treatment The body-weight remained *fairly* constant throughout, there being *only* a *loss of a few* pounds. Under dietetic treatment there was a decided reduction in the amount of urine and sugar excreted and this was further reduced by the phosphate of sodium The patient began to feel much better and spoke of going home at the end of June. The acetone smell in the breath continued however A faint albuminous cloud appeared later in the urine and on July 5th this became more pronounced and hyaline and granular casts *were found to be present. Soon* after admission the patient drank about 10 *pints* of liquid daily and excreted 351 ounces of urine, 10,000 grains of glucose, and 975 grains of urea. Under dietetic treatment he drank about 12 pints daily and excreted 245 ounces of urine, 6847 grains of glucose, and urea in about the former amount. These figures underwent a further reduction during the succeeding week. From June 18th to 24th when taking phosphate of sodium the patient drank daily eight and a half pints and excreted 181 ounces of urine, 5000 grains of glucose, and 840 grains of urea. These figures were still further reduced during the succeeding weeks or until July 5th. On the afternoon of this day, however, he complained of feeling drowsy and generally of feeling unwell and contrary to custom remained in bed all the afternoon. At 7.30 P.M. the drowsy feeling passed off. On the 6th at 8.30 A.M. he was again drowsy; the lips were cyanosed; the pulse was very rapid (166 per minute), small, and feeble (previously his pulse had been about 76); and the respirations were deep and sighing. He gradually passed into a semi-comatose condition. At 9 P.M. phosphate of sodium solution was injected. At 10.30 A.M. on the 7th the face and the surface of the body generally showed a purplish-blue mottling, respiration was very difficult, pain could be elicited on pressing over the region of the stomach, and he moved the head from side to side. The fundus of the eye when examined showed the retinal vessels as pale streaks At 4 P.M. the pulse was 160 and much weaker and irregular. A cardiac stimulant was injected with temporary improvement. Examination of the blood at this time showed that the red corpuscles were slightly "cloudy" in appearance and ran irregularly together without forming rouleaux. In the plasma an immense number of fine granules were present as well as clear highly refractile droplets which were half the diameter of the red cells. The specific gravity was 1036, the hæmocytes were 4,500,000, and the leucocytes were 23,800 per cubic millimetre. The hæmoglobin could not be estimated, as on mixing the blood with water it formed a semi-opaque liquid. On staining with osmic acid an immense number of fat droplets were demonstrated. At 9.30 P.M. a solution of carbonate of sodium together with strophanthin was injected and this was repeated every two hours subsequently. On the 8th the patient was completely comatose. Dr. G. A. Berry examined the eyes and found a peculiar and striking condition—namely, that the retinal vessels were white in colour, due to a change in either their contents or walls. The head was thrown back, the mouth was open, and the tongue was protruded. He died shortly after this. At the post-mortem examination all the serous cavities contained a large quantity of milky fluid. The blood which had escaped from the blood-vessels had a dirty-pink colour and the exposed blood-vessels, as on the surface of the brain, were white or reddish-white in colour along considerable distances of their course, as if they had been injected with wax. This condition was very markedly seen in the retinal vessels and when pressure was applied to them this white part moved along from place to place. The internal organs generally were healthy. There was a moderate amount of fatty degeneration of the liver which was most distinct at the periphery of the lobules. The hepatic capillaries were filled with this fatty matter when seen under the microscope. There were some congestion of the lungs and kidneys and great hyperæmia of the cardiac end of the stomach which contained some fatty-looking matter. The blood at first had a homogeneous dirty-pink colour. After standing in a vessel, however, it separated into two layers, a dark part below and a pale cream-coloured layer above, both nearly equal in amount. The liquid present in the pleural cavities (which was apparently an effusion) gave when it had coagulated even a larger proportion of the white material than did the blood. The President then showed lantern slides of the blood taken before the death of the patient in which it was seen that the granular matter was in reality due to particles of fat. A section of the lung showed that fatty particles filled the blood-vessels. In the liver and kidneys fat was also seen in capillaries. Nearly all of the internal organs exhibited great congestion, but it was the blood throughout all parts of the body which had undergone the most profound change. It contained an enormous quantity of fat in the form of minute granules. When subjected to quantitative analysis the fat present in the blood amounted to 16·5 per cent. as contrasted with from 0·2 to 0·5 per cent. in healthy blood. In ordinary cases of diabetes mellitus the proportion of fat in the blood was almost similar to that found in health. In a former case of diabetic lipæmia which the President had described in 1882, and in which he had determined during life the presence of a great mass of fat in the blood, the fat was present in the amount of 12·6 per cent. In other recorded cases it had varied from 1·3 to 11·7 per cent In the pleural effusion in the case now described the fat was in even larger quantity than in the blood, as it amounted to 20 per cent. The President briefly ran over the literature of the subject, stating that a Dr. Mariet of Edinburgh had noticed excess of fat in diabetics as early as 1799 In 1879 Professor Sanders and Dr. Hamilton had carefully recorded such a case and advanced the opinion that the coma and dyspnœa of so-called "acetonæmia" were due to fat embolism in the pulmonary vessels. This theory was not accepted at present, as there were many cases of diabetic coma without lipæmia. It did not appear that the presence of fat in the blood definitely modified the ordinary symptoms of diabetic coma. The particles of fat were so fine that they could transude into any of the cavities and at the body temperature they were perfectly liquid and so could not be concerned in the production of embolism. Lipæmia must be regarded as an accidental circumstance in the course of diabetic coma. In all probability the diabetic coma was itself due to the presence of acid bodies in the blood, being really an acid intoxication in which β-oxybutyric acid was the most potent factor. A coma indistinguishable from diabetic coma could be induced in animals by injecting this acid into their bodies or by a reduction in the alkalinity of their blood. From 100 to 200 grammes of this acid could be recovered from the body of a person who had died from diabetic coma. The alkalinity of the blood was reduced in the case just described *before* the onset of the symptoms. As regards the origin of the fat, it was not a manifestation of a general fatty degeneration. Moderate fatty change was present only in the liver, kidney, and myocardium. Yet fat was abundantly present throughout the whole vascular system. It could not therefore have been derived from the blood or tissues. Coincidently with the appearance of coma there was a marked reduction in the excretion of sugar. The urine obtained post mortem contained 2·5 grains per ounce. The abrupt fall in the sugar could not have depended on any alteration in the kidney. On July 5th and 6th the sugar had begun to undergo extreme chemical changes leading to a greatly enhanced production of butyric acid as well as to an enormous production of fat. The blood post mortem contained no sugar (neither did that of the case described in 1882). There was strong evidence that in diabetes the sugar in the blood might abruptly undergo chemical changes into acids and occasionally into fat also. As regards treatment both acetonæmia and lipæmia might be recovered from. If the fatty transformation as well as the acetonæmia was due to an acidosis then alkaline treatment was indicated. In this case, perhaps, an insufficient amount was injected or else so much fat and acid had been elaborated that no treatment could have sufficed. The President indicated that this alkaline treatment should be given in large amounts and on the earliest sign of the presence of oxybutyric acid and fat. The presence of the first could be gathered from an examination of the urine and of the second by the blood. The urine and blood should, he thought, be examined in diabetic cases every one or two weeks for β-oxybutyric acid and excess of fat respectively. A young diabetic patient might at any moment pass unexpectedly into a condition of the most serious danger.

Dr. LEWIS C. BRUCE read a paper entitled "Clinical and Experimental Observations upon General Paralysis." He said that in his previous communication to the society his conclusions were (1) that general paralysis was a disease directly due to poisoning by the toxins of bacteria the point of attack of which was through the gastric and intestinal mucous membrane; (2) that the poisoning was probably a mixed one, but the bacillus coli communis was apparently one of the noxious organisms; and (3) that the result of treatment by means of serum taken from cases of general paralysis in a condition of remission and injected subcutaneously into early progressive cases pointed to the fact that some form of serum treatment was the proper treatment for this as yet incurable disease. Further observations had led him to modify conclusion No. 2, that the bacillus coli communis was a cause of the disease. He now believed that bacillus coli infection was a secondary one. In the Perth District Asylum recent acute cases of general paralysis were rarely admitted and so the material for observation was therefore limited. Since the commencement of these observations Dr. Bruce had treated in all eight general paralytics with serum derived from cases of general paralysis in a state of remission. Three of these patients had made apparently complete recoveries. The patient in Case 1 had been discharged for three years and earned his livelihood as a saddler; the patient in Case 2 had been discharged for 18 months and was working in the Post Office; and the patient in Case 3 had been discharged for nine months and worked as a dyer. Of the remaining five patients one was relieved and had shown no progressive symptoms for four years. The remaining four were not improved. The leucocytes were regularly examined in two of the patients who recovered and in all the patients who did not improve. The only change noted was a continuous hyperleucocytosis during the period when the serum was being administered subcutaneously in two cubic centimetre doses daily. In the patients who recovered the leucocytosis fell to below 10,000 per cubic millimetre of blood and the percentage of polymorphonuclear cells was generally below 50. As according to his previous observations the blood of 70 per cent. of general paralytic patients contained an anti-body which agglutinated the bacillus coli communis in low dilutions of 1 in 10, he treated two cases with anti-bacillus coli serum. Neither patient benefited by the treatment. The leucocytosis induced by the subcutaneous injection of antibacillus coli serum was often very high, running to 40,000 per cubic millimetre of blood. Dr. Bruce next investigated the leucocyte changes which occurred in the various stages of the disease. In his first series of observations he had already recorded that in patients suffering from general paralysis there was a recurrent hyperleucocytosis. In a second series of observations made on six cases the fact of a recurrent leucocytosis was confirmed. Stained films showed that in the first stage of the disease the polymorphonuclear leucocytes were generally present in a percentage of 70 or 80. As the disease advanced these cells diminished in number until in the third stage of the disease they might fall as low as 40 per cent. As the polymorphonuclear cells decreased the lymphocytes increased. An eosinophilia was invariably present at some time during the course of the disease and varied from 15 to 5 per cent. of the total number of leucocytes. This eosinophilia was a sign that the disease was active; it was not present in patients who had passed into a definite remission or who had recovered. It was a fact that the course of general paralysis was often temporarily arrested if the patient suffered from some intercurrent inflammatory condition such as erysipelas. To ascertain if this arrest of the disease were due to the leucocytosis induced by the inflammation or to the specific anti-bodies formed in the blood and tissues Dr. Bruce made the following observations. Three cases of general paralysis, all with acute symptoms, were treated with small doses of streptococcus pyogenes toxin. The organism was grown on nutrient broth for a week at a temperature of 37° C. The culture was then killed by heat. This was then tested on rabbits to ascertain its virulence. Each patient then received half cubic centimetre doses of the fluid subcutaneously. Case 1, a male, showed no reaction in temperature, pulse, or leucocytosis and there was no mental benefit. Cases 2 and 3 both gave a mild febrile reaction (99° and 99 8° F. respectively) The pulse in both rose to 100; slight leucocytosis was present (14,000 and 15,000 per cubic millimetre). The polymorphonuclear cells rose above 80 per cent. and the eosinophiles fell to 1 and 2 per cent. The most marked result, however, was the mental effect. Both patients became quiet and sensible, recognised that they were ill, and submitted to treatment. The effect of the first injection passed off in a week, when it was noted that the percentage of eosinophiles was again increasing in the blood. A second and third injection gave exactly similar results and then the patients evidently became immune as further treatment yielded no result. After a due interval the toxins of the staphylococcus aureus prepared in the same way were injected but the subsequent reaction was feeble and gave no definite results. The fact that in Case 1, where there was no hyperleucocytosis, there was no beneficial action and that in Cases 2 and 3, with a hyperleucocytosis with high polymorphonuclear percentage, there was distinct benefit would seem to indicate that the increased polymorphonuclear leucocytosis was the active agent in assisting recovery. The fact of the rapid reaction to the toxins injected and the immunity quickly produced as well as the failure in reaction of the staphylococcus aureus would point to the fact that the toxins of the streptococcus had produced some anti-body in the blood and tissues which temporarily raised the resisting power of the patients. To ascertain if the increased leucocytosis alone were capable of arresting the disease, Dr. Bruce took Case 1 of the previous series, in which the patient had not benefited by serum treatment and observed the leucocytes, temperature, and pulse for several days. Two cubic centimetres of terebene were then introduced subcutaneously but with hardly any reaction and without benefit to her mental or physical condition. In the case of a male patient the reaction was marked; the leucocytes went up to 29,000 per cubic millimetre of blood; the polymorphonuclear cells were 80 per cent. There was great physical and mental benefit. In two months he was discharged to his friends. Two cases were treated with antistreptococcic injections of two cubic centimetres daily for over a month and both benefited temporarily but relapsed on discontinuance of the treatment. Dr. Bruce thought that the benefit was largely due to the leucocytosis induced. The results of these observations were, he thought, evidence against the theory that general paralysis was a disease due primarily to the breaking down of the brain neurons as the result of syphilitic poisoning and they supported the more recent view that the disease was due to the direct action of bacterial toxin which when temporarily overpowered allowed nature to put into force the constant attempts at recovery which were so marked a feature of the disease. Syphilis, plumbism, and great mental or physical strain were undoubtedly the predisposing factors, but without the direct bacterial attack there would be no such disease as general paralysis.—The discussion which followed this paper was brisk and in it the PRESIDENT, Dr. T. H. CLOUSTON, and Dr. W. FORD ROBERTSON took part.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Exhibition of Specimens.—Gynæcological Report of the Rotunda Hospital for the Year 1901–02.

A MEETING of this section was held on April 24th.

Dr W. J. SMYLY exhibited the following card specimens: 1. Two Myomatous Uteri weighing 9 pounds. The first was removed because of its size and continued growth and the second for pain and pressure on the rectum. 2. A Uterus which was removed for Cancer of the Cervix. 3. Tubes removed for Tuberculous Disease.

Dr. SMYLY also showed the following specimens: 1. Ovarian Papillomata. The patient was first seen on Oct 18th, 1902. The tumours, which were confounded with the uterus, on bimanual examination were supposed to be myomata. When seen on the 28th the abdomen was very much distended with ascitic fluid and the patient was suffering intense pain. Abdominal cœliotomy was performed on Oct. 31st. The abdominal peritoneum was studded with secondary growths and the omentum was a mass of disease. The two cystic ovaries, which were universally adherent, were removed with much difficulty and also the omentum. The patient recovered. 2. The patient from whom the specimen was removed was first seen in February, 1901. Though she had long passed the menopause a sanguineous discharge from the uterus had been going on more or less for two months. Curetting was advised but declined, and she was not seen again until six weeks previously, when a fungous growth was observed to be protruding from the os uteri. Vaginal hysterectomy was performed. The operation was a difficult one owing to the friability of the uterus, but it was successfully carried out and the patient made a good recovery. It was remarkable that an operation was still possible two years after the probable commencement of the disease. 3. This patient suffered intense distress from pelvic pressure and, the uterus being found enlarged and retroverted, the symptoms were attributed to the displacement. Abdominal suspension of the uterus by Kelly's method was performed, but owing to obstruction of the bowel the abdomen had to be reopened and the cause of the obstruction was found to be an adhesion of the rectum to the cervix, which it had been found impossible to separate at the original operation; the uterus was therefore allowed to return to its former position and the abdomen was closed. Her sufferings continued to be so great that she was obliged to relinquish her employment and when the removal of the uterus was suggested she readily consented to have the operation performed. About a fortnight previously Dr. Smyly performed a supravaginal amputation and the patient had made a good convalescence.

Mr. J. L. LANE showed a large Dermoid Cyst removed two months after confinement.

Dr. R. D. PUREFOY showed a specimen of (1) General

Follicular Enlargement of the Ovary; and (2) Rokitanski's Tumour of the Ovary.

Dr. PUREFOY read the Gynæcological Report of the Rotunda Hospital for the year 1901–02.—The discussion was postponed until the next meeting of the section.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—Meetings of this society were held on April 24th and May 1st, Mr. John Irving, the President, being in the chair.—Mr. J. Basil Hall read a paper on a successful case of Splenopexy.—Dr. E. Ward and Dr. P. Leech discussed the case and Mr. Hall replied.—Dr. Leech brought forward a case of Retro-peritoneal Hernia. The patient, a muscular man, 25 years of age, was seized in the early morning on a Sunday with violent abdominal pains. Two days later abdominal section was performed on account of intestinal obstruction when a left duodenal (retro-peritoneal) hernia was found, the sac containing about a yard of small intestine. The patient made a satisfactory recovery.—Dr. Ward, Mr. B. G. A. Moynihan, Dr. T. Churton, and Dr. J. B Hellier took part in the discussion and Dr. Leech replied.—Dr. J. Gordon Sharp read a paper on the Action of Morphine, Kino, and Calomel, illustrated by experimental and clinical evidence. In ordinary doses he believed that morphine was non-toxic to the patient after it had gone the round of the circulation. The loss of toxicity was not due to its rapid elimination by the urine, for if the ureters were tied and the drug was allowed to remain in the tissues there was no increase in toxicity. The loss of toxicity was probably due to the formation of a firm proteid compound of morphine which was not easily broken up. The fact that morphine could not easily be removed from the urine by the acetic and ethylic ether process in the presence of sodium bicarbonate supported this view of a combination of a proteid and the alkaloid. In future experiments Dr. Sharp intended to digest the morphine-laden urine with pancreatine and sodium bicarbonate and then to try to remove the morphine by the ethers. Going on to speak of kino, rhatany, and catechu he detailed some experiments which he had made with compound kino powder extending over long periods. The drug was given in five-grain doses in capsules before meals four times a day. The evacuations which previously had been dark, thin, watery, and frequent, now became pale, gluey, and less frequent. The motions were treated with absolute alcohol and examined after two days' maceration. The alcoholic extract on being examined was found to give no tannin or gallic acid reaction. The alcohol only appeared to dissolve the colouring matter of the kino (kino red). This body had lost its astringency. After some weeks' maceration the absolute alcohol was found to have precipitated the proteids and the tannin (kinoïn) of the kino was taken up by the alcohol. This tannin was only feebly astringent. It gave a reaction with ferric and ferrous salts. The urine gave no reaction with the combined iron salts, so it appeared that the drug when given in small doses only acted locally by forming a coagulum with the proteids, &c., and as it did so it gradually lost its astringency. This coagulum could only be broken up after prolonged maceration in alcohol. Calomel was next dealt with. The drug was found to be free from the perchloride when first obtained, but in from six weeks to two months it gave the reaction for the persalt. By experiment it was found that this change could be produced rapidly by digesting the calomel with cat's stomach—in several hours This action might explain why calomel acted so energetically and in small doses in flesh-eating animals. In human beings the salt might act energetically or not at all and much depended on the condition of the stomach at the time as to pepsinogen and acid. The purgative action might be a reflex one, as where the stomach contained much ferment and acid vomiting was set up, peristalsis followed and the contents of the canal were evacuated. Calomel, however, did not always act as a persalt. It might be transformed into a soluble mercurous proteid salt. The experimental evidence pointed this way, for when calomel was digested with active saliva or with fresh extract of calves' pancreas a solution was obtained which could be dialysed through parchment and passed through filter paper and when so treated and examined it gave a black precipitate with caustic potash, a green with dilute potassium iodide solution, and reacted to the electrolysis test. These tests proved the presence of a mercurous salt and of a soluble mercury salt.—Dr. Churton, Mr. T. H. Fox, and Mr. C. Richardson took part in the discussion and Dr. Sharp replied.—Dr. Bedford Pierce read a paper on the Treatment of Atonic Dilatation of the Stomach. The principal features of the treatment which he had adopted in a very severe case were the continuous application of heat and the persistent administration of food without restriction of solids or liquids. The treatment was introduced into this country by Dr. T. Taylor of Ealing and came from Switzerland where it was practised by Dr. Stendall. The patient should be placed under favourable conditions as regarded rest and freedom from worry and the recumbent position should be insisted upon for the first week or two. He should attempt no work and at first should not read or write. Stimulants, tea, and coffee were prohibited. No drugs of any kind were given. The heat was applied by relays of hot-water bottles day and night. The diet should be liberal, consisting largely of milk, eggs (yelks only), meat of all kinds (including pork), fresh and stewed fruit, macaroni, and farinaceous foods. Food should be taken and persevered with regardless of discomfort. A case was related in which dyspepsia and constipation had existed for 20 years and in which frequent attacks of colic had resulted in abandonment of work. The patient had had the best medical advice, had been to the Cape, had spent five weeks in a nursing home, and had taken complete rest for three months, but all without benefit; he had become profoundly emaciated. In the course of three months' treatment he gained three stones in weight, the constipation disappeared, and the stomach, which had previously reached below the umbilicus nearly to the crest of the ilium, retracted to its normal position. In discussing the merits of the treatment Dr. Pierce suggested that the heat promoted more efficient peristalsis and that the rest enabled the patient to digest more food than had been possible before. He deprecated the use of concentrated foods but considered ordinary food with an abundant indigestible residue without any restriction of liquids or solids the proper diet for atonic dilatation, provided there was no sign of ulcer or gastritis.—Dr. J. E. Eddison, Dr. Churton, Mr. S. Walker, Dr. A. Mantle, Mr. H. Littlewood, Dr. A. Christy Wilson, Dr. F. W. Eurich, Mr. R. L. Knaggs, and Mr. Richardson joined in the discussion and Dr. Pierce replied.—The following officers were elected for the session 1903–04:—President: Mr. Richardson. Vice-Presidents: Dr. A. Bronner and Mr. Ward. Treasurer: Dr. Eddison. Librarian: Dr. A. G. Barrs. Auditor: Dr. C. M. Chadwick. Committee: Dr. J. Gordon Black, Dr. W. A. Evans, Mr. E. Roberts, Dr. A. H. Bampton, Mr. W. Thompson, Dr. J. W. H. Brown, Dr. J. G. E. Colby, Dr. S. M. Hebblethwaite, Mr. J. H. Woods, Mr. Irving, Dr. G. I. Swanson, Mr. J. J. Pickles, Mr. Edward Ellis, Mr. H. de C. Woodcock, and Mr. Michael A. Teale. Honorary secretaries: Dr. E. F. Trevelyan and Mr. Knaggs.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on May 1st, Mr. Rickard Lloyd, the President, being in the chair.—Mr. J. R. Lunn read notes of an obscure case of Intestinal Obstruction due to an Obturator Hernia. The patient, a widow, aged 61 years, was admitted into St. Marylebone Infirmary on Dec. 30th, 1902. She was very obese. The pulse, the respiration, and the temperature were normal, the tongue was clean, and the abdomen was not distended. She was slightly jaundiced. On the right side there was a reducible femoral hernia. Nothing was found on examination by the rectum or by the vagina. 24 hours after admission the patient began to vomit fæcal matter, the tongue was dry and furred, and the symptoms suggested some obscure cause of intestinal obstruction. On opening the abdomen the small intestines were found to be distended and covered with lymph. Towards the left iliac fossa the small intestine was found to be collapsed and apparently bound down to the pubes. During the examination fæces welled up from the left iliac fossa. A distinct fulness was then discovered in the upper part of the left thigh below Poupart's ligament. On incising this swelling a piece of gangrenous omentum was found which was ligatured and removed. The clamped ends of the intestines were then brought up into the abdominal wound, three inches of the ulcerated gut on each side of the perforation were removed, and a Murphy's button was introduced. The abdominal cavity was washed out with saline solution and the wound was closed with silkworm gut. The operation lasted two hours and the patient died a few hours later from peritonitis and cardiac syncope.—Mr. E. Percy Paton and Mr. G. Twynam discussed the case.—Dr. J. E. Squire continued the adjourned discussion of his paper on the Modes of Cure in Pulmonary Tuberculosis. After pointing out that the arrest or the advance of the disease was determined by the nature of the reaction changes in the tissues and so depended upon what they called the resisting power of the tissues, Dr. Squire said that the aim of modern treatment was to strengthen this resisting power and to kill or to remove from the body the causative micro-organisms. Thus their efforts might be directed towards strengthening the resisting powers of the cells and tissues of the body, so enabling them to withstand and to destroy the bacilli, or they might attempt to destroy the bacilli by germicide and antitoxic remedies. A knowledge of pathology assisted them in determining which mode of attack to select. One of the early results produced in the lung by the tubercle bacillus was to block up not only the alveoli but also the blood and lymph channels in the affected area. Thus, blood-borne antiseptics, as well as any that might be inhaled, were prevented from reaching the stronghold of the bacilli. Such treatment would, however, destroy any bacilli that escaped from the focus of the disease and thus prevent extension. The antiseptics used, however, could only be of moderate strength. Antitoxin treatment was looked upon by many as the main hope of the future, but there was a wide difference between the short sharp fight with the diphtheria bacillus and the prolonged struggle in tuberculosis. Tuberculin seemed to be dangerous; it appeared to increase the rapidity of the tuberculous process, and in the majority of cases safety was to be sought in the slower processes which led to the formation of fibrous tissue. X rays, sun baths, and electric currents had been used without any convincing measure of success. For the arrest of the disease the alternative principle of treatment by assisting the tissues of the body to resist the bacilli offered better hope of success. Of the hygienic requirements fresh air claimed primary attention, but certain other aids to hygienic treatment deserved consideration. Among the processes which tended to limit the action of the tubercle bacilli an increase in the wandering cells was important; thus anything which tended to leucocytosis might have a very beneficial effect. With this object cinnamic acid, hetol, and nuclein had been used The excess of proteid food which was taken in forced feeding was also said to produce leucocytosis. Food was certainly required in full quantity, but it was its assimilation which was important and it might be necessary to remedy a faulty digestion. With regard to cough it was generally better to prescribe expectorants to make the cough effective than sedatives to check it In conclusion Dr. Squire considered that drugs should be used as auxiliaries only to help the patients to get the fullest benefit from hygienic treatment.—Mr. R. W. Lloyd mentioned a case in his experience in which alleviation of symptoms, and to some extent of the signs, of phthisis had occurred as a result of the patient keeping her windows widely open day and night. At the same time the discovery of scars in the lungs post mortem had shown that cure used to occur before the value of open air was recognised.—Other members continued the discussion and Dr. Squire replied.

Laryngological Society of London.—A meeting of this society was held on May 1st, Dr. P. McBride, President, being in the chair.—Dr. Atwood Thorne showed a case of Epithelioma of the Larynx which had been previously shown in January. The interest of this case was that a certain amount of improvement had taken place under the administration of potassium iodide and mercury. When the patient was seen in January last the left cord was absolutely fixed and there was a growth of the left arytænoid extending to the left arytæno-epiglottic fold. Under this treatment the left cord had recovered a fair degree of mobility and the continuous growth had shown as two growths with an intervening space and a submaxillary gland had become distinctly smaller. Latterly, however, the case had [illegible] left cord had become [illegible] occurred.—Dr. W. H. [illegible] Fauces in a fem[illegible] sented was very [illegible] but the fact that [illegible] syphilis, either pr[illegible] been treated for five months with anti-syphilitic remedies with no benefit and that latterly some improvement had resulted from the administration of arsenic led Dr. Kelson to form the opinion that the disease was lupus.—Mr. R. Lake exhibited (1) a case of Ulceration of the Tonsil involving the Posterior Faucial Pillar in a woman, aged 35 years; (2) a microscopical specimen of a large Papilloma in the posterior aspect of the cricoid cartilage which was the apparent cause of obstruction in a case of carcinoma of the upper end of the œsophagus; and (3) a Papilloma from the region of the inferior turbinal with absorption of the internal antral wall.—Dr. J. Donelan showed a case of Subglottic Thickening of the Vocal Cords in a man, aged 38 years (? pachydermia).—Mr. E. B. Waggett showed a case of Primary Tuberculosis of the Nasal Septum in a man, aged 35 years (with microscopical specimen). The patient had [illegible] of pain in the nose and f[illegible] and exhibiting an exter[illegible] diameter. A specimen taken from the edge of the ulcer showed tuberculous tissue with well-developed giant cells. Examination of the chest revealed merely increased vocal resonance at the right apex behind and in front. There was no history of cough or of hæmoptysis. The symptoms had existed for two years.—Dr. E. Furniss Potter exhibited a case of Swelling in the Postnasal Space in which the diagnosis lay between syphilis and malignancy. It was impossible to obtain any history of symptoms—sore-throat and dysphagia—dating further back than three weeks previously.—Dr. J. Dundas Grant showed a case of Chronic Laryngitis with Papillary Thickening of the Vocal Cord.

Rochdale and District Medical Society.—A meeting of this society was held on May 6th, Dr. J. Melvin being in the chair —Dr. J. A. Ashcroft made some remarks on Puerperal Eclampsia. He considered it to be the best practice not to induce labour but to rely on medical treatment.—Mr. G. W. Malim invariably had recourse to bleeding in eclampsia, and out of a considerable experience he had never had a fatal case.—Dr. A. Wallace also spoke of the efficacy of bleeding.—Mr. H. H. I. Hitchon gave an account of a rapidly fatal case of Hodgkin's disease. A well developed boy, aged 12 years and nine months, was first seen on Feb. 23rd, supposed to be suffering from mumps. The swelling had been first noticed four weeks before and had increased. The boy felt well but easily became tired. The family history was good. The upper cervical glands on both sides were much enlarged, the lower cervical glands were enlarged to a less extent, and the axillary and femoral glands were slightly enlarged. The glands were comparatively soft, neither painful nor tender and not matted together. The spleen projected one inch below the costal margin, the liver was not enlarged, and the bones were not tender. The patient was distinctly anæmic. He became rapidly weaker and four days later was confined to bed. Two days later still he was very weak and almost colourless, his evening temperature being 103° F. The glands were considerably larger and the spleen reached to midway between the costal margin and the umbilicus. The abdomen was large but not tender. The patient vomited small quantities of blood and submucous hæmorrhages were observed on the palate and tonsils. The breath was foul. On the next day the cervical glands had still further increased and the spleen had enlarged another inch. On the following morning vomiting of large clots of blood occurred, followed by fæcal matter, and death took place. The total duration of the case was five and a half weeks. The blood was not examined and a post-mortem examination was not obtained.

Kidderminster Medical Society.—A meeting of this society was held on May 1st, Mr. J. Lionel Stretton, the President, being in the chair.—The President showed a number of specimens and patients, among the latter being a woman, aged 49 years, on whom he had performed Gastrojejunostomy for Malignant Disease of the Pylorus; the approximation was accomplished by means of a Murphy's button which had not at the date of the meeting (one month after the operation) been passed. The patient had made a good recovery, had gained 8 pounds in weight, and was [illegible] gall-stones were evacuated; these he considered had been imbedded in the thickened omentum, having previously ulcerated through the gall-bladder.—Dr. Addenbrooke also showed a case of Progressive Muscular Atrophy in which the right hand and forearm were chiefly affected; all the muscles of the right hand and thumb were much wasted. The muscles of the forearm had improved under galvanism. The patient was a man, aged 25 years.—Mr. A. C. Oldham read a paper on Some Diseases of the Naso-Pharynx.—A discussion followed.

Reviews and Notices of Books.

Diseases of Women: A Clinical Guide to their Diagnosis and Treatment. By GEORGE ERNEST HERMAN, M.B., F.R.C.P. Lond., Obstetric Physician to, and Lecturer on Midwifery at, the London Hospital; Examiner in Midwifery to the University of Cambridge and the Royal College of Physicians. New and revised edition with upwards of 250 illustrations. Demy 8vo. London: Cassell and Co. 1903. Pp. 884. Cloth, 25*s*.

As some six years have elapsed since the appearance of the first edition of this Clinical Guide to the Diseases of Women we are glad to see that Dr. Herman has brought out a new and revised edition. It is true that very little alteration or emendation has been found necessary, but that may well be taken as a proof of the excellence of the work. On page 83 a new section has been added upon the surgical treatment of chronic ovarian pain. The author states that in very bad cases the vicious circle of effects which occurs in such patients can at times only be broken by removing the ovaries. The results of ignipuncture are disappointing and resection of part of the ovaries is often followed by the return of the pain, so that in extremely bad cases the removal of one or both ovaries is the only thing that brings relief. Such an operation is obviously only justifiable as a last resort.

In considering the surgical treatment of cancer of the cervix Dr. Herman lays stress upon the importance of avoiding inoculation of the wound surfaces with portions of the cancerous growth. He advises as a preliminary step that the growth should be thoroughly curetted and cauterised. He then recommends the method of performing vaginal hysterectomy with hemisection of the uterus practised by Doyen. We are glad to see that the more surgical method of ligation of the broad ligaments has been substituted for the use of pressure forceps. We do not, however, agree with the author in his practice of hemisection of the uterus in performing vaginal hysterectomy for cancer of the cervix. If the growth mainly involves the lower part of the cervix no doubt it is possible completely to curette and to cauterise it; but if, on the other hand, it has begun in the upper part of the cervix and the external os is not much involved, then it is almost impossible completely to curette the growth away or to cauterise thoroughly the whole of the raw surface left. In such a case hemisection of the uterus is extremely likely to expose a fresh portion of the growth from which infection of the wound surfaces may well occur. Doyen's method of splitting up the uterus is peculiarly applicable to cases of fibroid tumours of the uterus and cases of hysterectomy for chronic pelvic inflammation, but it is, we think, both unnecessary and unsuitable for most cases of carcinoma of the cervix. The section upon the surgical treatment of fibroid tumours of the uterus has been almost entirely rewritten. Dr. Herman recommends amputation of the body of the uterus, commonly known as "supravaginal abdominal hysterectomy," and when performing panhysterectomy he thinks that the best method is that of Doyen. Myomectomy he considers the ideal operation when the patient is young and, failing this, one or other of the varieties of hysterectomy.

The book is one of the best clinical works upon gynæcology in the English language, and the present edition fully maintains the high standard of the first. There is a familiar error which we are surprised to see in a book by so careful an author as Dr. Herman—viz., Gärtner for Gartner. In Figs. 197 and 198, copied from Mr. Alban Doran's book on Tumours of the Ovary, Fallopian Tube, and Broad Ligament, the "umlaut" is correctly omitted. We had hoped that in a new edition many of the very crude and inartistic illustrations would have been replaced by others more worthy of the letter press. This has unfortunately not been done, although a few new figures have been added.

Surgical Anatomy: a Treatise on Human Anatomy in its Application to the Practice of Medicine and Surgery. By JOHN P. DEAVER, M.D., Surgeon-in-Chief to the German Hospital, Philadelphia. Vol. III. (pp. 816): Abdomen, Pelvis, Thorax, and Lower Extremity. London: Rebman Limited. 1902. The three vols., with 499 plates, price six guineas net.

THIS is the third and concluding volume of this exhaustive and bulky treatise. Like the first two volumes it is profusely illustrated, the number of full-page plates in this volume being no less than 178. As all the drawings have been prepared from dissections specially made for the purpose of this treatise the amount of labour expended both by dissectors and artists must have been immense and the author must be almost unreservedly congratulated on the result of his labours. There is, however, one point in connexion with the illustrations which calls for comment: there is a most striking and unnecessary difference in the scales to which some of the pictures have been drawn. A comparison, for instance, of the representations of the kidneys, liver, and spleen gives an altogether erroneous idea of the relative sizes of those organs, the bulk of the spleen appearing far greater than that of the other organs mentioned. The size of the heart, too, varies quite unnecessarily in successive representations of it. These variations are the more misleading since the scale to which the figures are drawn is never indicated.

In dealing with applied anatomy, as distinguished from anatomy proper, the difficulty is to know where to draw the dividing line. The author of the present work has evidently encountered the same problem. He has adopted the plan of giving anatomical descriptions which, when compared with those usually met with in works of this kind, are unusually full. The result is that the work appears to contain much more of ordinary anatomy than of its application. At the same time, the fact that anatomy is dealt with so fully gives rise to a disposition to criticise the book from a purely anatomical standpoint, which, perhaps, is hardly fair. Be that as it may, the fact remains that visceral anatomy has made huge strides in recent years, particularly since the adoption of formalin and other methods of hardening the viscera *in situ.* Now the bulk of the volume under review is devoted to a consideration of the anatomy of the abdomen, thorax, and pelvis, and we do not find overmuch of this recent knowledge reflected in the text. This is possibly because the preparation of the volume was commenced some time ago, but at the same time it is to be deplored as detracting in a measure from the value of the book.

Just as it is difficult to separate applied from systematic anatomy so, on the other hand, it is difficult to separate it from surgical technique. The author has been fairly successful on this score, although we find in places details which appear to belong more properly to a treatise on surgery. For instance, we find minute directions given for the performance of vaginal and abdominal hysterectomy and other operations together with details on suturing which seem quite unnecessary and out of place. What is the aim of the book? We gather from the number of illustrations, from the character of the anatomical descriptions, and especially from the minute directions given for *dissection*, that the treatise is intended to teach the surgeon anatomy as well as some of its practical applications All this should surely be unnecessary if anatomy is learned in its proper place and at the proper time—we mean in the dissecting room during the earlier years of studentship If it is not then learned no series of illustrations, however excellent they may be, and no book descriptions, however full, can adequately supply the deficiency We much doubt if such a sumptuous volume as this will ever find its practical use in the dissecting room. Despite the points we have criticised, the book is a monumental production and possesses a wealth of detail The amount of work lavished on it has evidently been very great Its usefulness is enhanced by the presence of a very complete index in which, by the use of heavy faced type, the plates illustrating each organ and region are at once indicated Curiously enough, we could find no plate indicating the position of the ovary

Diseases of Women By E C DUDLEY, A M, M D Third edition, revised and enlarged With 474 illustrations, of which 60 are in colours, and 22 full page plates in colours and monochrome London Henry Kimpton 1903 Royal 8vo, pp 761 Price 21*s* net

THE appearance of a third edition of Dr Dudley s work upon the Diseases of Women is a proof that it has met with appreciation from students and practitioners The author has made numerous corrections and alterations and has very thoroughly revised the work Many of the chapters have been rewritten and others have been recast and transposed to other parts of the book A large amount of the letterpress has been arranged in the form of tables and parallel columns with a view to make it more useful to students for class work and to practitioners for reference Among the most interesting additions are the figures illustrating many of the major and minor gynæcological operations For example the consecutive steps in hystero myomectomy are shown in 12 drawings salpingectomy in five drawings, vaginal hysterectomy in 15 drawings, ovariotomy in eight drawings, and curettage in five drawings The total number of illustrations has been increased by 21 and a considerable addition has been made to those in colours and to the full page plates Drawings illustrating operations are undoubtedly useful but at the same time they tend to minimise the difficulties of technique and hardly ever give a faithful representation of the conditions as they are met with in actual practice A good instance of this is seen in Plate XI, representing ligature of the broad ligament in vaginal hysterectomy. The device of using an ordinary needle held in a needle holder and passed through the broad ligament blunt end first is undoubtedly ingenious and should prove useful at times Dr Dudley does not approve of the more radical methods of removing the uterus for malignant disease recommended by many modern surgeons As he points out, removal of the peri-uterine glands and the lumbar glands and excision of the broad ligaments close to their base undoubtedly add to the traumatism, are often attended with much difficulty, and require a very prolonged operation attended with a corresponding increase in the amount of shock

The method of placing the chief diagnostic features of different conditions in tables is undoubtedly useful but must always be taken with a certain amount of reservation For instance, we find that the chief distinctions in the diagnosis of a case of hydramnios from an ovarian cyst are given as follows In hydramnios the student is told that there is evidence of pregnancy, rapid development of the tumour, ballottement, and symmetrical distension of the abdomen, while in a case of ovarian cyst there are no signs of pregnancy, a slow development of the tumour, no ballottement, and unilateral distension of the abdomen He is not told that in many cases of hydramnios the evidences of pregnancy are difficult to obtain, nothing is said as to the method of obtaining ballottement in such a case, and the statement that an ovarian tumour sufficiently large to be mistaken for hydramnios causes unilateral distension of the abdomen is more often found in a text-book than confirmed as a clinical fact at the bedside Many of these tables are, however, exceedingly good and should prove most useful to the student in summarising his knowledge

The work has been considerably enlarged and improved since the appearance of the first edition and is now a very excellent manual of its kind The want of proportion in the amount of space allotted to various subjects still seems to us to exist but to a much less extent than it did We are glad to see that the chapter on Pelvic Massage has been considerably curtailed and partly rewritten We still think that too much detail is given in the treatment of injuries to the pelvic floor and to the cervix, but no doubt we are influenced by the views held in this country as to the importance of such traumatism The illustrations, especially some of the coloured ones, are very good, but many more of the original ones might well have been omitted or replaced by better drawings

---

LIBRARY TABLE

Book on the Physician Himself By D W CATHELL, M D Philadelphia F A Davis Co 1902. Pp 411 Price $2 50 —This is the eleventh edition of the original work and has been revised by the author and his son Dr W T Cathell It is written in a cheery, breezy style and shows wide reading, for it swarms with quotations Be this as it may, it contains many valuable pieces of advice upon such subjects as quackery and the practitioner's duty to his patients, to his fellow practitioners and to himself Allowance being made for the differences in social customs which exist in Great Britain and the United States, practitioners, and especially those just entering practice, will find many valuable hints in this book

Rate Supported versus Voluntary Hospitals By J G CRAGGS, M V O, F C A London The Scientific Press, Limited 1903 Pp 37 Price 1*s* 6*d* net.—This pamphlet is an expansion of an article by Mr Craggs which appeared in the *Times* of April 7th and upon which we commented in our issue of April 11th, p 1044 We have nothing to add to what we then said except that in the light of the figures and facts, which are quoted more fully in the pamphlet than they were in the article, we should say that if every subscriber to the Hospital Sunday and Saturday Funds were to read and to digest both facts and figures the amounts received by the two funds in question would be doubled

The Annual Charities Register and Digest, 1903 London Longmans, Green, and Co Pp ccviii -734 Price 5*s* net —This is one of the annuals which come out year after year at a standard pitch of excellence and hence the reviewer's work consists in praise Mr Loch's introduction is in itself a "Summa of almsgiving Every kind of charitable organisation or institution is classified in the book before us and therefore no one has any excuse for giving to undeserving charities We think, as we have said upon previous occasions, that some of the "spiritual institutions" might be eliminated from a book dealing with charities For instance, neither the Church Association nor the English Church Union has any right to be called a charity and so with other institutions which we find in the section of "spiritual."

The Victualling of the Royal Navy Past, Present, and Future By ALEXANDER TURNBULL, M D Edin, Inspector General of Hospitals and Fleets (retired) London Elliot

Stock. 1903. Pp. 31. Price 1*s.*—This little pamphlet is compiled "from State papers, historical documents, official sources, &c., and a seventeenth century private diary not hitherto published," and is an extremely interesting work. The victualling of the navy in Georgian, and even in early Victorian, times was by no means above reproach, but the new scale of victualling which comes into operation this year seems very good. Readers of Marryat will remember Mr. Chucks's opprobrious epithet of "burgoo swilling" applied to the unhappy cooper who had lurched against him. "Burgoo," or "bargow," is described by Surgeon Thomas Trotter, M.D., R.N., 1792, as thick gruel made of oatmeal. Oatmeal, however, no longer forms part of the ordinary ration but is retained for stokers to be mixed with water as a drink.

The City of London Directory, 1903. London: W. H. and L. Collingridge. Pp. 1194. Price 12*s.* 6*d.*—In the preface to this directory, which is the thirty-third annual edition, it is stated that it "is the only annual volume containing valuable and exclusive information in regard to the City of London, the Corporation, the Livery Companies, and other public bodies." With this statement we acquiesce, as we think that in this respect the Directory is a valuable book of reference, but we consider that the remaining portions could be improved. We notice, for example, that a firm of well-known carriers is called Pickford's (lim.), that the British Photo-Engraving Co. is called the British Photo-Engineering Co., that in one case at least "Verulam" is spelled "Verulum," that in one instance at least the old address of a firm is given from which they removed some months ago, and that in the Street Directory "Bishopsgate-street Without" is continued on the next page as "Bishopsgate-street Within." We may also point out that THE LANCET is published on Fridays and not on Saturdays, as stated in the Newspaper List. On the whole, however, the present issue is an improvement on that of last year.

How and Where to Insure. By CHARLES COX. London Effingham Wilson. Pp. 125. Price 1*s.*—The greater part of Mr. Cox's useful work was contributed to the *Empire Review*, where he writes under the pseudonym of "Thrift." He appears to have an excellent grasp of his subject and to have written in the interests of the would-be insurer and not in that of any particular office. Therefore his deductions are the more worthy of consideration, and, in our opinion, cannot fail to be useful in guiding to the successful choice of a suitable office in any particular class of insurance.

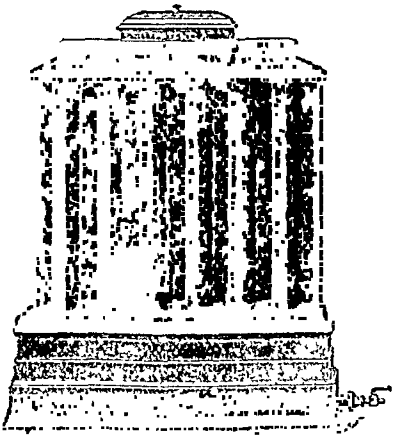
JOURNALS AND MAGAZINES.

The Medical Journal of the Italian Navy.—The first issue of the *Annali di Medicina Navale* for the present year appears in the form of a double number owing, we are informed in a prefatory note, to the fact that some important and richly illustrated articles have taken more time in preparation than was anticipated. In order to compensate subscribers for the delay the editor consequently decided to publish the parts for January and February under a single cover and he has, moreover, endeavoured to improve the quality of the journal by making it respond more adequately to the labour of his collaborators and by rendering it more worthy of the sympathetic reception which is accorded to it by the medical public—foreign as well as Italian. So manifold and complex are the duties imposed on medical officers of the Italian navy that the editor would not have felt surprised had they entirely failed to furnish him with material. That some among them did supply him is an example of the utmost zeal and self-abnegation. Had they only the necessary time to collect and to arrange their clinical notes what a rich and useful harvest would be reaped by the *Annali.* The double number thus introduced contains several articles of merit evincing much labour, but there is nothing specially referable to the navy or to naval matters. A feature of the periodical consists in a review of current medical literature. The synopsis is not only copious but well arranged and reflects much credit on the compilers and translators.

New Inventions.

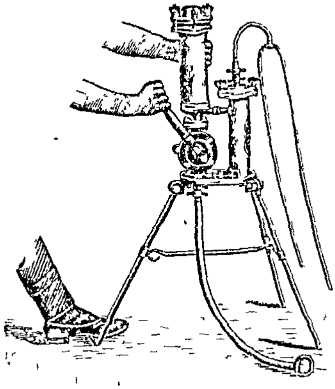
THE "SPEEDON" HOT-WATER RADIATOR.

THERE are one or two important advantages connected with the use of this appliance for warming apartments that are well worth attention. The apparatus consists in reality of a series of tubes communicating with each other and up and down which a rapid circulation of hot water is maintained. The heat of the water radiates readily into the room owing to the great radiating area which the stove presents. The surfaces of the columns are zig-zag, thus 〰. The radiator which we tested contained almost exactly three gallons of water. The source of heat is an atmospheric gas-burner consuming, according to our observations, about 4½ cubic feet of gas per hour. We found that it takes a little over two hours to raise the water from ordinary temperature to the boiling point, that is to say, at the expense of rather less than 10 cubic feet of gas. All this time there is a steady emission of heat into the room. As a matter of fact, when the water has reached to within a few degrees of boiling point the gas may be turned down, the water serving to distribute the heat of the gas flames in a uniform and regular manner. This principle of heating by means of gas is well adapted for bedrooms as there need be no danger of gas escaping or of objectionable fumes arising. Thus the gas may be lighted an hour or so before retiring and at the time of retiring the gas may be turned off altogether, when the radiator will continue to warm the room for some time and no anxiety need be felt as to gas fumes or as to the working condition of the burner. According to our experiments it takes quite four hours before the stove cools down to the temperature of the room again. A flue is provided to carry the products of combustion up the chimney, but as we have already said the stove requires no attention after the gas has been turned out, it then continuing to exert a marked warming effect upon the room. The appliance is thus economical, effective, and safe. The Speedon radiator is manufactured by the Coalbrookdale Company, Limited, of 141, Queen Victoria-street, London, E.C.



THE BROWNLOW FIELD SERVICE FILTER.

THIS filter has been designed especially for transport purposes. It may easily be packed in a wicker basket which can be strapped to the pack saddle. The dimensions of the basket are 2 feet 3 inches in length, 14 inches in width, and 10 inches in depth. A glance at the accompanying illustration will show that the filter consists practically of three sections. The filtering-tube is contained in a copper jacket which communicates with a clarifying filter immediately above a semi-rotary pump. The water enters the hose at the bottom by the suction caused by a few strokes of the rotary pump and then passes into the clarifying cylinder which, as shown in the illustration, is grasped by the left hand of the operator. The clarified water is then discharged into the sterilising filter, germ-free water escaping ready for drinking purposes at the two pipes shown. The clarifying cylinder contains an inside case of gauze and two clarifying bags. The sterilising cylinder contains an unglazed porcelain filtering tube or candle which, according to the experiments of Professor G. Sims Woodhead and Dr G. E. Cartwright Wood, prevents the transmission of disease germs when worked under proper conditions, so that it was concluded that this filter would protect against the transmission of water-borne disease. Excellent attention, we find, has been paid to details, bearing in mind the special uses of this filter. It is compact, very easily put together, and all the parts are well made and of solid construction. One field-service filter is sufficient, it is stated, for the needs of a unit of 100 men and one man at least in each section is expected to superintend its management. The rate of pumping should not exceed 20 to 35 strokes per minute and in the event of the rate of filtration becoming slow a new clarifying bag should be introduced and, if considered necessary, a new cylinder also. Instructions to this effect are supplied with each outfit The manufacturers are Messrs. Slack and Brownlow of Gorton, Manchester.

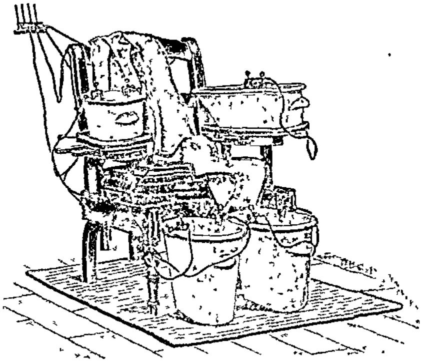


"OCCILANA" CLOTH.

THE manufacturers of "Occilana" cloth have afforded us an opportunity of examining it at various stages in its preparation and samples of fabric have been submitted to us representing first the unscoured fleece with the natural oil retained, secondly the yarn spun ready for weaving, and finally the finished material. Chemical and microscopical tests throughout determined at once that the fabric is all pure wool The wool is said to be produced entirely in the west of England Further, no evidence was obtained of the presence of irritating substances in the form of injurious dye stuffs or of any residue of objectionable bleaching agents. The material is warm and comfortable and porous, though shower proof. It has been pronounced a cloth material of good quality by a cloth expert. The cloth may be had in a variety of patterns and is supplied by Messrs. S Fisher and Sons of 215, 217, and 219, Regent-street, London, W.

A FOUR-CELLED ELECTRIC BATH.

THE four-celled electric bath, devised by Dr. C. E. Schnée of Carlsbad and shown in the illustration, presents no intricate complications either in the arrangement of its parts or in its therapeutic use. It may be said to consist of two principal portions—namely, (1) an armchair capable of adjustment in a variety of positions; and (2) a set of four basins or small baths, two of which stand on the floor, while the other two stand on the arms of the chair. The patient uncovers only his arms and lower legs and sits in the chair with each of these limbs in one of the baths. The baths are filled with water or medicated solutions, and in each of them two carbon electrodes dip into the liquid. When the patient's limbs are immersed it is obvious that a current may be sent through his body in either direction from any bath to any other one, or even from any one to the other three collectively, so that a diversity of combinations is offered for the choice of the medical attendant. These variations of direction can be made instantly by means of moveable plugs fitting into holes in a switch-board, in addition to which arrangements are provided for measuring and regulating both the quantity of the current (in milliampères) and its intensity (in volts); these two conditions may also be variously combined, so that a current of small quantity may have a high intensity and *vice versâ*. In each of these baths the effective electrode is of course not the carbon conductor but the liquid contained in the bath The current is therefore applied to the whole of the immersed surface, which for the upper limb might amount to 1200 square centimetres (186 square inches) and for the lower limb might amount to 1400 square centimetres (217 square inches) For many therapeutical purposes it is desirable to have electrodes of considerable size and the above-mentioned areas of skin are much greater than those of the metallic electrodes usually employed. Galvanic, faradic, or sinusoidal currents may be used; an alternating current may be previously changed into a direct one by means of a transformer. Currents having a quantity of from two to about 30 milliampères and an intensity of from 10 to 45 volts may be employed. Cataphoresis, or the introduction of medicinal substances into the system by electrical transference through the skin, can be easily accomplished by filling the baths with the proper solutions Dr Schnée states that from the year 1896 to the end of 1902 he has treated 2577 patients with this apparatus.



IMPROVED CONTINENTAL SERVICES.—By a new express service passengers travelling by the Harwich-Hook of Holland Royal British mail route now arrive at Berlin much earlier than hitherto; leaving London (Liverpool-street Station) at 8 30 P.M. Berlin is reached at 6 43 next evening. Corridor carriages and restaurant cars run between the Hook of Holland and Berlin. By this new service communications with other north German towns, with Saxony, Austria, Russia, and Sweden have been much improved and accelerated Passengers from the northern and midland counties of England leaving in the afternoon can travel directly to Harwich alongside the steamers, thus saving the trouble and expense of crossing London. A dining-car and through corridor carriages run between York and Harwich, also through carriages to and from Manchester and Liverpool *viâ* [illegible] London and North-Western and Mi [illegible] return journey to [illegible] be effected by the [illegible]

THE LANCET.

LONDON: SATURDAY, MAY 16, 1903.

The Address in Medicine at the American Medical Association.

IT must always be interesting to the members of any profession to be put in a position which enables them to contemplate work kindred to their own as it is influenced or modified by conditions of society somewhat differing from those of which they have experience. On this account, even if on no other, we should welcome the Address in Medicine lately delivered by Dr. ANDERS of Philadelphia at the meeting in Chicago of the American Medical Association—an address purporting to be on "Social Conditions in America in their Relation to Medical Progress and Disease." The title is an ambitious one and seems to justify expectation of a very comprehensive survey of the fields of medicine, of pathology, and of therapeutics. We cannot say that this expectation is altogether fulfilled; for, in truth, a large part of the address is somewhat vaguely declamatory and, although full of sounding phrases, seems to leave us destitute of any very definite information upon the subjects with which it may be presumed to deal. We are told, indeed, that "our possession of unclassified facts is increasing with uncomfortable rapidity," but we receive a very slender modicum of information as to the general nature of these facts or as to the precise directions in which it is expedient that their classification should be attempted. We are told, again, that "epoch-making discoveries and important, far reaching scientific effort *is* justly the boast of the American profession"; but the discoveries in question are not described in detail nor is any reason given for assuming that "far reaching scientific effort" is in any way peculiar to America. The discovery of the anæsthetic properties of ether might, indeed, be called "epoch-making" by any who were so left to themselves as to use the term at all, but where are the rest? It is well known that SHAKESPEARE was an American citizen, but can the same claim be substantiated with regard to HARVEY, or JENNER, or PASTEUR, or LISTER? These are men whose discoveries, if they have not made epochs, have at least marked them and whose names will still be regarded with veneration by their countrymen in future generations, although not, we trust, with boastfulness—a state of mind antipathetic to science and calculated rather to prevent than to promote discovery.

With regard to the general social conditions of America, as they bear upon the preservation or the restoration of health, the address gives us very little precise information, and it may well be that the author has thought it unnecessary to dwell upon facts which were more or less familiar to his audience. It is, indeed, said that "the universal spirit of haste has taken possession of our professional life," and that "the cure must result from a readjustment of the home life and habits of the professional and other classes." This would mean, we are told, "a return from our present-day restlessness and rush to a quieter period, to a 'Mansfield Park,' with its charm of quiet village life; a return to a normal life with natural intellectual tastes, and to calm, patient, original observation that fosters vital force and successful endeavour." Surely the placid spirit of JANE AUSTEN would be perturbed if it were made acquainted with such a description of the state and surroundings of MRS. NORRIS and the BERTRAMS. The title of the address led us to hope for information upon the relations in America between the medical profession and the large classes of people to whom the payment of adequate medical fees would be impossible. Our readers know only too well the difficulties which the problems hence arising offer to older societies and the slender amount of success which has hitherto been achieved in dealing with them. In England the medical officers under the Poor-law are very inadequately paid and the whole system of club and dispensary practice is riddled by scandalous abuses for which, so far, neither reason nor agitation has succeeded in suggesting any sufficient remedy. In Germany matters are even worse. A letter lately appeared in the *Times* in which the writer gave a highly interesting account of the effective manner, as he regarded it, in which the problem of medical attendance on the labouring classes had been solved in that country and in which he said that the German workman had determined to banish squalid poverty from his class. By his subscriptions noble hospitals and convalescent homes had been erected and were maintained and generally a sort of golden age in relation to sickness had been inaugurated. It has since appeared that the physicians employed by the societies into which German industry has been organised for the accomplishment of these wonders have been ground down to starvation point, that their remuneration has been at the rate of about twopence a visit, and that they have at last formed a counter organisation which threatens a universal "strike" of the medical profession against the societies if more reasonable terms are not previously agreed upon. The same question, although possibly under a slightly different form, must of necessity present itself in America, and it would be a matter of extreme interest to learn whether any solution of it has been reached. The very absence of any reference to the subject, in an address bearing the title which we have quoted, seems at least to show that the friction hence arising cannot be so great in America as it is in this country or in Europe.

When Dr. ANDERS passes away from questions of a very general character it is to call attention to certain phenomena in relation to disease which seem to us to be of great significance. He dwells upon a considerable recent increase in cancer, affections of the kidneys, and fatty and fibroid degenerations. Coincidently, he tells us, with the advent of epidemic influenza, there has been a heavy death-rate in Philadelphia from lobar pneumonia; and he gives a table showing the results of post-mortem examination in 275 cases of death attributed to this cause which occurred in the Philadelphia Hospital. Of these, 250, or about 90·9 per cent., showed cardio-vascular lesions, principally chronic endocarditis and general atheroma of the vessels. Chronic interstitial nephritis was noted in 52·7 per cent., chronic parenchymatous nephritis in 18 per cent., and acute nephritis in 13·8 per cent. It is highly probable, of course, that the pre-existing cardiac or renal disease may have been largely contributory to the fatal issue in these cases and that post-mortem examinations of a more general kind would have shown very different results. But these, such as they are, surely indicate a wide prevalence of the degenerations produced by alcohol and point to the extensive and far-reaching influence in the great cities of America of the agent which is, perhaps, the chief cause of premature *mortality amongst ourselves. Dr. ANDERS does not himself* offer any explanation of the facts which he records, but we can hardly be mistaken in the opinion that they justify an earnest endeavour on the part alike of philanthropists and of physicians to bring home a knowledge of the deleterious effects of alcohol to the classes which, in the present state of civilisation, are on the whole most liable to suffer from them.

Back to the Land.

THE paper read by Mr. RIDER HAGGARD at the weekly evening meeting of the Royal Institution on May 8th presented to his hearers in a condensed form a very interesting portion of the facts and conclusions dealt with by him in his recently published work on "Rural England." Mr. HAGGARD applied the title of "Rural England" to his lecture also, but he intimated when he began that he could only treat certain aspects of so large a subject in the time at his disposal. The particular points to which he accordingly devoted his attention were principally those arising out of the debated question of small holdings. Mr. HAGGARD discussed the prevalence of these in comparatively recent days and put forward evidence to show that in times of which no definite records are available small holdings were successfully owned by men who, whether they lived hard lives or not, at all events got a living out of a few acres of land that was their own. With the practical possibilities of small holdings in modern times he dealt at some length; after pointing out the extent to which small holdings have disappeared, he turned to the question as to how they might be re-introduced. The personal observation which Mr. HAGGARD has brought to bear upon the topics which he has now studied for a considerable time with great energy and industry enabled him to enforce the various views which he put forward by practical illustrations of value, and he enjoyed the advantage of being a skilled narrator who could tell his story so as not only to inform but to interest his audience. *None will disagree with Mr. HAGGARD* as to the importance of the matters that he discussed, both from the point of view of those who desire that our country should provide from its own soil a larger proportion of the food-stuffs which it consumes, and from that of those who regard with apprehension the crowding of the population into the towns, where neither the natural law of supply and demand nor legislation has yet obtained for them anything approaching adequate accommodation. Mr. HAGGARD spoke of the land and its interests as receiving little care from Government because those interests are divided and do not speak with any political voice, and he expressed the belief that now, more than ever in our history, they are vital to the welfare and safety of our nation. Of the physical results to the public health arising out of the flocking of the rural population to cities, where it fails to a large extent to find the comparative prosperity which it seeks, Mr. HAGGARD said: "It means that the character of the race is changing; it means that their physique is deteriorating; it means that fewer men of the best class are available for purposes of national defence ...... it means a new race of city-bred Englishmen the victims *of various diseases which, it is alleged, kill them out within* three generations. We know what country-bred Englishmen have done in the past and the height to which they have lifted their race and nation. Can so much be expected from their descendants if they are to be herded together in the most dismal and airless quarters of our great cities?" In conclusion, he confessed to feeling somewhat "lonesome" in the task which he has imposed upon himself of calling attention to the present position of rural England and its population. We may, however, express the hope that among those who study the results of his labours he will find some who will be struck with the practical possibilities of the remedies that he suggests. Those who acquaint themselves with the working of Sir R. PEARCE EDGCUMBE'S experiments in Dorset, with Major POORE'S experiments in Wiltshire, and with the conditions prevailing at Downham in Cambridgeshire, to all of which Mr. HAGGARD calls attention, may be inspired to effect something similar. Even a Government might be induced to assist upon terms that would make its assistance of practical value, bearing in mind that the difficulties arising from overcrowding in towns, already almost insuperable, may be to some extent diminished in future by anything which keeps the rustic population at home.

A "Plague Goddess" in Bombay.

To us of the West the workings of the Eastern mind are often unfathomable. In the simplest matters, as in the most recondite, it is clear that their ways are not our ways or their thoughts our thoughts. Not only is their point of view different, not only do they accept as facts what we look upon as the baseless fabric of a vision, but even when there are premisses accepted by both different conclusions may be drawn. From Bombay comes a tale exhibiting strikingly the tendencies and fallacies of Eastern thought and showing results which may well appal those who have at heart the extension of our modern hygienic ideas.

For nearly seven years many parts of India have been ravaged by plague and of all large towns affected by it few have suffered more than the city of Bombay. In their tens, their hundreds, nay, in their thousands, the victims of this pestilence have succumbed, but still the plague flourishes. The habits of the people are so opposed to all sanitary laws that no surprise need be felt at the continuance of the disease. Efforts have been made to restrict the spread of the malady and at one time the decree went forth that patients suffering from plague should be taken to isolation hospitals and there tended with all the skill and science that the West can give. The attempt, however, was in vain; the people declined to accept the ostensible reason for the segregation of the sick and various explanations fanciful in the extreme were bruited abroad to account for the anxiety of the Government to take care of those affected. The result was that cases of plague were not reported and that when house-to-house visitations were made the plague-stricken were hidden so that the health officers were often unable to find them. In other cases forcible resistance was offered to the removal of the sick. Thus the plan defeated itself and the Government reluctantly suspended the order for the isolation of those suffering from plague who were left in their airless hovels to spread infection to their crowded families. Still, notification of cases became easier and some attempt could be made to supply medical assistance to the afflicted. There is no epidemic disorder with a higher mortality than plague; the death-rate is generally over 70 per cent. and sometimes even nine-tenths of those attacked may succumb. To the uninstructed native mind a disease with such a heavy mortality can only be looked upon as the direct act of the gods and it can only be satisfactorily treated by incantations and magic rites. Methods like these appeal to them far more readily than the hygiene and medicines of Europe. The fatalism which is so characteristic of uneducated peoples forbids them to entertain for a moment the idea that these epidemics can be prevented by fresh air, pure water, and cleanliness, and their aspirations after miraculous cures make them the easy dupes of self-assertive charlatans. In Bombay towards the end of February of this year a novel form of imposture made its appearance. A woman, some 45 years of age, Bhagirathi by name, announced that she had become "possessed" by the Goddess Maha Kali and she made proclamation that she had seen with grief the seven years' plague which had decimated the city and caused intense and widespread misery. Now, however, a happier era was dawning, for as the incarnation of Maha Kali she had come to save the city of Bombay. To purge the city of the pestilence the Government should give to the poor a maund of rice and "dal." She herself was to ride through the town seated on a buffalo, a "jatra" or fair was to be held in her honour, and for two days all business must be suspended—not even a single train must run. Should, however, the Government disdain to hearken to her counsel the only way in which she could display her divine power was to cure any plague patients taken to her. With what must be supposed to be miraculous foreknowledge she had rented, a few days before she was possessed by the goddess, some land in front of her hut where she built a mandap and she also erected an open shed. A large saffron-coloured flag and band of music served to enhance the attractions. The news of the arrival of this "plague goddess" spread rapidly through the city and it was not long before accounts of marvellous cures which she had wrought were freely circulated, and it is probable that these lost nothing of their miraculous character as they spread. Wonders so great could not be confined to Bombay; they spread to the neighbouring towns and reached even to greater distances. As a result patients were taken to her in great numbers, so large crowds collected to see the "cures" performed. We have no record of the number of patients who at first sought her aid, but during 18 days in March 839 sick persons were taken to her. Of these 667 were cases of plague, but there were also five cases of small-pox and two of measles. The remainder were mainly cases of chronic enlargement of lymphatic glands common in India as elsewhere. The patients were taken in every possible way. Some were well enough to walk even from places far off. Others were carried on the backs of loving relatives or friends, but many arrived in public carriages. The "plague goddess" did not condescend to treat every case taken to her and there were naturally much crowding and pushing as the friends of each patient tried to put him forward for early treatment. No attempt was made by Bhagirathi or her assistants to keep apart the sick and the healthy and the risk of contagion may be imagined.

The mode of treatment adopted is barbarous and revolting. The patient lies stretched out on the ground. Bhagirathi places herself by his side and applies her mouth for many minutes to the enlarged inguinal gland which she sucks vigorously, but the skin is not broken and no blood is drawn. Then the inflamed and tender gland is rubbed energetically with her foot and later with her hands. A betel nut is taken and pressed on the bubo with her foot and then kicked away. Powdered red lead is smeared on the swelling and on the patient's forehead and brushed with a twig and he is made to stand up. The "goddess" deals him three severe blows on the forehead and these are repeated by her assistant, and the patient is sent away after a donation of flowers, fruit, and money has been made. From time to time during the treatment Bhagirathi is seized with convulsions and only the arms of her two attendants save her from falling to the ground. The cases which she prefers to treat are instances of simple chronic glandular enlargement, for the sight of the patient able to walk away sound does much to enhance the popular belief in her superhuman powers of treating plague. When a case of true plague, however, is treated the results are disastrous. In one case examined by the executive health officer of Bombay the bubonic swelling had extended by the next morning to six inches around the gland and a cellulitis had evidently been set up. The massage cannot but serve to hasten the passage of the plague bacilli from the lymphatics into the blood stream and the chance of recovery must be materially diminished. Some true plague patients went on foot and since any exertion during this disease is very dangerous it is not surprising that some of these fell down dead near the hut of Bhagirathi. Within one month 23 persons died thus close to the temple of the "goddess." So much for the harm done to the patient himself, but what about the harm to others? The opportunities for the spread of the disease are numerous, the gathering together of crowds in times of epidemics is always to be deprecated, and especially harmful is it to associate large numbers of the plague-stricken with many not yet affected by the disease. Moreover, as we have seen, patients with other infectious disorders such as small-pox and measles are liable to be taken for treatment and thus these diseases also are likely to be spread. The employment of public carriages, too, for the conveyance of patients cannot but be dangerous and many were thus employed, for in 19 days 326 public carriages were seen to take patients to BHAGIRATHI. The whole neighbourhood also ran risks of infection, for statistics have shown that the number of cases of plague occurring in the district where the "goddess" resided showed a very marked increase after her miraculous cures had commenced. Attempts were made to put an end to these barbarous practices. Under the Municipal Act the health authorities apparently have no power and therefore they gave information to the police. BHAGIRATHI was brought before the second presidency magistrate, and evidence was adduced that her mode of treatment and the crowds to which it gave rise were calculated to spread widely plague and other infectious diseases. The magistrate, however, dismissed the case as he held that the "goddess" could not know that plague was infectious, since she had not contracted the disease in spite of being brought into close contact with affected persons. Also the magistrate could not see that bringing large crowds of persons together, the sick with the healthy, was liable to spread the disease. By this amazing decision the "plague goddess" and her abettors were permitted to continue their dissemination of the plague. We are, it is true, not aware of the exact channel by which the plague bacillus gains entrance into the body, but of its communicability there can be no doubt. Two courses were then open to the police. An application might be made to the High Court for revision of the case, but this was a cumbrous and dilatory method of procedure and ultimately it might not be successful, and meanwhile the evil would continue. The other course was a direct appeal to the Government through the municipal commissioner of the city of Bombay. This was done and the Government resolved that the police should again prosecute BHAGIRATHI and her assistants. Fortunately the case was heard in the court of the chief presidency magistrate and the woman was convicted and fined 100 rupees and an injunction was granted restraining her from continuing her "cures," but these procedures took a month to complete and during this time hundreds of plague patients went to her for treatment.

We congratulate Dr. J. A. TURNER, the executive health officer, and also Dr. S. C. HORMUSJI, the divisional health officer, and the other officials concerned on the ultimate success of their efforts; but the whole matter shows the lack of wisdom in attempting to deal with uneducated populations, especially in times of epidemics, by means of the elaborate and cumbrous legal machinery which may be suitable to more highly civilised states of society. The folly of the magistrate who first heard the case needs no further comment from us

Annotations.

"Ne quid nimis."

ST. BARTHOLOMEW'S HOSPITAL.

THE Lord Mayor's committee of inquiry into the affairs of St. Bartholomew's Hospital met on May 5th at the Mansion House under the presidency of the Lord Mayor. The report of the subcommittee on administration and finance was discussed, the conclusions of the report being summarised as follows:—

> [illegible]
>
> further loss of income.

After discussion of the report the following motion was unanimously agreed to:

> That this committee, having carefully considered the report of the subcommittee on the financial and administrative management of the hospital [which is summarised in the "conclusions" given below] are of opinion that the governors have [illegible]
>
> ing the hospital up to modern

All the friends, and they are many, of the oldest hospital in the United Kingdom will be glad to see that the committee is of opinion that the "reputation, character, and administration of the hospital" have been completely vindicated, but possibly everyone will not agree with the recommendation that the public should be appealed to. A public appeal would probably divert a certain amount of money from other deserving charities and we ourselves have said in a former issue[1]: "It seems to us better for the public that St. Bartholomew's should temporarily bear the burden of a debt to the bank than that supplies which are the very life blood of other charities should be jeopardised." The hospital, however, is at present a City institution, although it benefits the country at large. It was originally served by a religious house and its revenues came out of money given to the Church, which was mostly taken away from the Church by Henry VIII. at the Dissolution of the religious houses. We think that an appeal might well be made to the heads of those great families whose founders received Church lands.

THE MIDWIVES ACT AND THE TEACHING OF OBSTETRICS.

IN his introductory address to a course of lectures on Obstetrics at the Owens College, Manchester, Dr. W. Japp Sinclair made several references to the Midwives Act and to the work which lies before the Central Midwives Board of which he is a member. The Act, it will be remembered, only came into force on April 1st and the board has consequently not yet had time to complete the large body of rules, the making of which may be said to form its first duty, and these when framed by the board have to be approved by the Privy Council which is to consider any representations made with regard to them by the General Medical Council. Dr. Japp Sinclair was therefore precluded from speaking in detail of the work done and to be done by the board, but he was able to forecast in general terms the changes which the Act might be expected to bring about. With regard to the midwives themselves he looked to the Act as destined ultimately to abolish the "Gamp" throughout the country, removing the practice of midwifery from the hands of "the illiterate widow, the elderly housemaid, the innominate drudge of country districts," and placing it so far as it is to be practised by persons not members of the medical profession in the hands of those who, he submitted, should not be altogether illiterate. For example, he suggested that the certified midwife should be able to read a manual, to write a report of a case, and to have such acquaintance with the rule of three as to enable her to prepare an antiseptic solution or to dilute a baby's milk in the same degree on two successive occasions. The Act itself Dr. Japp Sinclair evidently looked upon as far from perfect although capable of amendment and improvement, but he expressed the belief that the changes brought about by it might in the future be found to exercise considerable influence upon the teaching of obstetrics in medical schools. In considering the course of training generally adopted in this country for this branch of medical study he drew unfavourable comparisons between English practices and the superior efficiency which he claimed for German methods. The Midwives Act is beyond question a measure which leaves to the board which it has brought into being a very wide discretion in the framing of the regulations by which alone the Act will become effective and many will study these with interest besides the class directly concerned in them. Although we have referred to the Act as having come into force on April 1st our readers are aware that that date only marked the commencement of the powers of the board the most immediate duty of which, as we have pointed out, consists in the framing of rules. It is not until April 1st, 1905, that a midwife not certified under the Act is precluded from taking or using the title of midwife or any name implying that she is certified under the Act and consequently there is no immediate urgency for the certification and registration of those who are permitted by the Act to be certified without being examined under the regulations of the Central Midwives Board. They have to comply with the necessary formalities in the course of two years from the date of the Act coming into operation but are not obliged to do so before. It is not until April 1st, 1910, that every woman practising as a midwife will have to be certified. As, however, the women who may desire admission to the roll of midwives by means of the training and examinations to be imposed by the board will require time in which to prepare themselves that body is no doubt proceeding as rapidly as circumstances will permit with the framing of the necessary regulations.

INTERFERENCE WITH A MEDICAL WITNESS.

AT an inquest held at Acton on May 5th upon the body of a clergyman who had been found in his bedroom shot dead with a revolver lying near him a medical witness made a complaint to the coroner of a nature which is happily unusual. Mr. D. M. L. Campbell, after giving his evidence, asked the coroner whether it was right that a medical man summoned to give evidence at an inquest should be visited two or three times with reference to what he might be about to say and should receive a letter or letters suggesting that his examination of the body had not been careful and that he should make another. It was further suggested to him that a clergyman would not commit suicide. The coroner very properly and very naturally expressed his strong disapproval of what had been done and refused to listen to an explanation which was tendered, no denial of the accuracy of Mr. Campbell's statement being made. The coroner's observations can hardly have been too severe for the occasion. Mr. Campbell pointed out that to him, as he had been personally acquainted with the deceased, the task of making the examination and giving evidence had been exceptionally sad. In any case, a medical practitioner in such circumstances has thrust upon him a painful duty incidental to the practice of his profession and he is entitled to the protection of the court before which he appears. Mr. Campbell, according to the report of the inquest in the *Acton Gazette*, said: "When I was called I went into the room and the body was lying supine. He was lying on his back with his head inclined a little to the right side. The legs were straight out and the little and index fingers of the right hand were resting on the floor, whilst the revolver was in the position in which it had been grasped, although it appeared to have slipped from the grasp. There was a wound behind the right ear. The direction of the wound was forward and onward." In answer to direct questions from the coroner he gave the opinion that the wound was self-inflicted and that it could not have been accidental. He also added that the hair was singed. There may be a slight error in the report quoted as to the course taken by the bullet, but this does not affect our view of Mr. Campbell's position. It will be perfectly clear that the medical witness who observes facts such as these is obliged to include them in his evidence and is entitled to draw the deductions recorded. It was open to the relatives and friends of the deceased through their legal representative to cross-examine Mr. Campbell and this they did propounding a theory of an unintentional discharge while the deceased was cleaning the revolver and supporting their theory with evidence, apparently to the satisfaction of the jury who found a verdict of "Accidental death." That they should have taken the other course of seeking to influence Mr. Campbell in his evidence is a matter which they should now regret. A medical witness called at an inquest is a member of an honourable profession, occupying a position which renders him independent of all prejudice. He is summoned to give evidence as to facts observed by him and to express opinions which his training and experience enable him to form. The jury is not bound to adopt his view in their verdict, but he is not to be interfered with in expressing it without fear or favour.

THE PATHOLOGY OF GASTRIC ULCER.

MANY theories have been proposed to explain the origin of true gastric ulcer which was first distinguished as an affection *sui generis* by Cruveilhier. Some have attributed it to the action of the gastric juice, some to disturbances of the circulation such as are seen in thrombosis and in septic and aseptic embolia, and others again to the attacks of micro-organisms; but in 1874 Dr. Durante, recognising its affinity with the "*mal perforant*" of the foot, pointed out that in both instances the tissues affected were predisposed to disease in consequence of deep-seated disturbance of the nerves distributed to them. The subject has again been taken up by Dr. R. Dalla Vedova of Rome who has endeavoured to determine, by means of resection of the vagi and of the solar plexus (from which sources the stomach receives its nervous supply) or by the injection into these structures of an aseptic fluid such as concentrated alcohol, the effects of the suppression of nervous influence upon the nutrition of the stomach. He found that about half of all the animals operated on exhibited distinct changes in the gastric mucous membrane. This effect was not due to the toxic action of the alcohol causing acute septic peritonitis without any characteristic microscopic inflammatory changes, for no less than two-thirds of the animals survived for ten days; nor was it due to exposure of the intestines to cold or to any mechanical injury to the parts, since these were not, and need not be, touched in extirpation of the cœliac plexus. Dr. Dalla Vedova considers himself to be justified, from a careful consideration of all the circumstances, in drawing the conclusion that the necrotic ulcers of the gastric walls observed in his experiments were directly due to the lesions inflicted on the abdominal sympathetic. The ulcerative processes were noticed to affect chiefly the antrum pylori, and many drawings accompany Dr. Dalla Vedova's article showing the position of the ulcers, hæmorrhages, spots of necrosis, and cicatrices of ulcers that were seen after the death of the animals. This position of the ulcers he attributes in part to the more highly acid reaction of this segment of the stomach and in part to the constant irritation of the several tunics debilitated by the loss of their nervous supply owing to the passage over them of the more solid parts of the chyme in the later stages of digestion.

The size of the necrotic spots varied from that of a pin's head to that of a lentil, they were more or less circular and they were elevated on an œdematous and hyperæmic area. The hæmorrhages were small and varied in colour from yellow to blackish brown and the ulcers were funnel shaped, extending through the whole thickness of the mucous membrane, the base being formed by the muscular coat Their borders were fairly well defined and on the depressed surface was some necrotic detritus A German translation of Dr Dalla Vedova's original article, which was contained in the report of the sixteenth annual meeting of the Società Italiana di Chirurgia which was held at Rome in 1900 has recently appeared in the *Archiv fur Verdauungs Krankheiten*, Band viii, Hefte 3, 4, and 5

THE KING'S SANATORIUM

A SITE for "King's Edward VII's Sanatorium' has been acquired from Lord Egmont at Lord's Common, Easebourne, six miles south of Haslemere and about three from Midhurst. The site is 150 acres in extent and contains in its northern and eastern portions a magnificent fir wood Towards the south and sheltered by the wood is a natural open plateau over 450 feet above sea level and commanding in the distance a beautiful view of the South Downs Upon this the sanatorium will be erected Behind the ground gradually rises until at the northern extremity of the property a height of 620 feet is attained Complete shelter from north and east winds is thus secured To the west and immediately adjoining the site is an open common of considerable extent, which will add materially to the usefulness of the institution The lower greensand is the geological formation. A delay in acquiring the site was occasioned by the difficulty experienced in obtaining a due supply of water, but by impounding springs about a mile away to the north of the site this difficulty has been overcome and an abundant supply of water of great organic purity, as tested both bacteriologically and chemically, has now been obtained Mr H Percy Adams, F R I B A, the architect appointed by the advisory committee who has recently by its direction made a very careful study of sanatoriums both in Germany and Switzerland, is now preparing his plans

PUBLIC HEALTH LITERATURE

IN another place we publish under the heading of "The Aerial Convection of Small-pox' a letter from Professor Antony Roche, and certain points raised in that communication have a general interest for the public health services As regards the literature relating to the aerial convection of small pox, we venture to think that there will be found in the numbers of THE LANCET, either in editorial articles or in our abstracts of the annual reports of medical officers of health, references to most of the literature which is really of importance Moreover, the reports of societies dealing with public health and epidemiology will also be found in our columns But the main point in the communication under consideration is the suggestion that the Local Government Board should publish annually a *résumé* of the reports furnished by the medical officers of health throughout the country Apparently, a suggestion in this sense was made to the late Sir Richard Thorne whose only objection to the course was the expense which it would entail, more particularly if a copy of such a publication were to be sent to every medical officer of health in the country Although it does not appear to us that a *résumé* of all the reports is called for, seeing that but a small proportion thereof contain matter of any interest to those outside the district concerned, we quite agree that a useful purpose might be served if the Local Government Board could be induced to publish annually a volume of the more interesting points contained in the reports of medical officers of health Possibly a deputation to Mr Long might assist this matter But what we think is of at least equal importance is that the annual reports of the medical officer of the Local Government Board, which contain not only selected reports by the medical inspectors but also the records of valuable bacteriological and chemical research, should be made more accessible to medical officers of health Unfortunately, the price of these volumes is somewhat prohibitive but if they could be presented to medical officers of health or supplied to them at a reduced price a very material service would be rendered to the public health service It would be well in the event of Professor Roche's suggestion being carried out that the annual volume which it is proposed to establish should contain selections not only from English public health literature but also from the reports relating to the more important foreign cities But public health literature, more especially if it be held to embrace bacteriology, covers in these days a very wide field and the volume in question would be likely to run to very bulky proportions As regards the reports of the medical inspectors of the Local Government Board, Professor Roche will find notices thereof from time to time in our columns and all these reports can be purchased for a few pence from the Government publishers, Messrs Eyre and Spottiswoode Unfortunately, the annual reports of medical officers of health cannot, as a rule, be so purchased, but there would seem to be no sufficient reason why this should not be arranged for in the future

THE PUBLIC SALE OF INDELICATE PRINTS AND OFFENSIVE LITERATURE.

A PICTURE that looks well and can be properly appreciated in the hallowed precincts of an academy may not look so well or refined when reproduced in the form of a cheap engraving and sold openly in the public streets We have noticed for some time past that at regular periods in the streets of the city there seem to be epidemics of the sale of bad literature and suggestive prints, and only this week we saw reproductions about two feet long of a well known picture which is a study of the nude being openly offered for sale at a penny each not a mile from the Stock Exchange We are afraid that in many cases the purchaser, who may be a small boy with a penny to spare, is not likely to possess that subtle discrimination generally only the outcome of a mature mind and refined nature, which appreciates only the artistic beauties of such a picture and rejects all grossness Again, pamphlets are often sold in the city streets either really obscene or professing to be so and often possessing an alluring cover as a bait to entice purchasers to taste of the carrion within The gutter merchants who sell such noxious wares should receive attention from the police

OPERATION FOR EXTRA-DURAL HÆMORRHAGE FROM WHOOPING-COUGH

IN the *New York Medical Journal* of April 25th Dr G S Brown has published a case which is not only important as a contribution to the scanty literature of the cerebral complications of whooping cough but also appears to be unique in the fact that an operation was performed for cerebral hæmorrhage from this disease A healthy boy, aged seven years, had whooping-cough The paroxysms were pronounced but not severe After four weeks he complained of pain in the head and became irritable. On the next day, when Dr Brown first saw him, he was suffering intensely from pain in the right temple "The pain was so severe as to suggest rupture of a vessel, particularly as there was sufficient somnolence to arouse suspicion." On the following morning at 3 o'clock he was in great pain, somnolent, and semi-delirious with a slow pulse, a temperature of 103° F., and complete paralysis of the left arm. A hypodermic injection of morphine gave some relief until 10 A.M., when another was given. At 3 P.M. he had a slight convulsion; at 9 P.M. the somnolence had increased. The pain was agonising and was much increased by the attacks of coughing, for which one-twelfth of a grain of heroin hydrochloride was given every four hours. The question of operation was considered but postponed in consequence of lack of precedent. Although almost narcotised from the heroin he had a severe left-sided convulsion at midnight which was followed within an hour by two more, each more prolonged and severe than the last. As his condition was alarming and as it seemed clear that a clot was pressing on the right motor area of the cortex he was trephined an inch above, and in front of, the parietal eminence. The opening in the skull was extended towards the middle of the Rolandic area and the dura mater was opened but nothing could be found. The child's condition was not favourable to further search and it was hoped that the opening would relieve the pressure. On the next day all the symptoms except the paralysis had improved, but 48 hours after the operation there were three convulsions in quick succession. The patient was trephined again nearer the median line. The dura mater was opened to the extent of an inch but nothing could be found. It was immediately sutured. Upon cutting away a piece of bone from the trephine opening a clot was found. Owing to its small size it was thought at first that the clot might have been a result of the first operation, but an hour after its removal the patient moved his arm and the limb was as strong as ever two days later. Recovery was uninterrupted. The hæmorrhage was extra-dural and was supposed to come from the middle meningeal artery.

THE PREVALENCE OF SMALL-POX.

Small-pox shows but little sign of decreasing. Last week the number of cases at Salford showed a decided rise and it continues to spread in the West Riding. In Dublin there is a great tendency to conceal the existence of cases and this renders the work of the health authorities very arduous. In London on Friday, May 8th, there were 57 cases of small-pox in the hospitals of the Metropolitan Asylums Board, as compared with 44 a week previously. At a meeting of the Poplar borough council held on May 7th the following case was reported by the medical officer of health, Mr. F. W. Alexander:—

> A male, aged 32 years, was detained at a surgery in the Roman-road and removed suffering from small-pox on April 20th. (See footnote.) The patient, apparently in good health, had returned home from a hospital in Bath on the 9th inst., where he had been an inmate for five weeks. On the 15th inst. he became ill, rash appeared on the 17th inst., and as stated above was removed on the 20th inst., so that he had been lying at home for six days suffering from small-pox. In the same house living with him were his wife, a daughter aged 16 years, and six unvaccinated children. These children had been playing in the streets with other children and neighbours had been going in and out of the house. Information was also given that a child, aged 18 months, on the 18th inst. was sent from Ford-road to Ellesmere-road, Bethnal-green; notice was at once given to the Bethnal-green authorities. All the inmates have been removed to the Council's shelter, Glaucus-street, and the house will be cleansed and disinfected throughout. The mother requested that the six unvaccinated children should be vaccinated. The public vaccinator was communicated with, but it is questionable whether vaccination will be of any use, as the children had been exposed to infection for six days. Another child, aged eight years, unvaccinated (making seven in all) was brought into the shelter on the 21st inst. from Chisendale-road; he had been taken there on the 20th inst. The medical officer of Bethnal Green was communicated with. It was evident to the medical officer of health that the disease must have been contracted out of the district, and thinking that in the institution at Bath from which the patient was discharged there may be other inmates with the premonitory symptoms of small-pox, the medical officer telephoned through to the institution at Bath, and was informed that two cases of small-pox had been removed on the 16th inst. and others since. If the telephone answer received be correct it is a pity that the authorities of the institution at Bath did not communicate with all the local authorities to which patients had been discharged within the 14 days previous to the 16th April, then the patient at Ford-road would have been discovered on the 17th inst., and chances of the spread of the disease lessened.
>
> Footnote.—From information since received the small-pox patient went to the London Hospital, was placed in an isolation ward pending making inquiries, as he was seen to have small-pox, and arrangements were about to be made for his removal but he made his escape.

We are glad to see that the borough council warmly commended Mr. Alexander for the prompt way in which he had dealt with this case. Mr. Alexander now informs us that already nine other cases of small-pox have been traced to this patient, so we earnestly hope that when he is recovered the sanitary authorities will prosecute him for exposing himself while suffering from a dangerous infectious disease.

RESIGNATION OF DR. POORE.

We regret to announce that Dr. G. V. Poore, Professor of Clinical Medicine in University College, London, and physician to University College Hospital, has found it necessary to resign his appointments in consequence of ill-health. Dr. Poore's brilliant work as a physician and a practical sanitarian is well known to all our readers and he has well earned by 35 years of able and unceasing toil the good wishes of all his profession. Now that he is relieved from heavy official duties the loss of University College will be the gain of his patients and their medical advisers, as he will be able to give more time to his private work.

GANGRENOUS CHOLECYSTITIS.

In the *American Journal of the Medical Sciences* for April Dr. John H. Gibbon has published a case of the very rare condition of gangrenous cholecystitis. A woman, aged 52 years, was admitted to hospital on Oct. 3rd, 1902. She had suffered from frequent attacks of indigestion, accompanied by nausea and vomiting. Her illness began three days before admission with pain in the left hypochondrium and vomiting. On he evening of admission the temperature was 102° F., the pulse was 112, and the respirations were 32. She complained of pain and tenderness in the left side of the abdomen. The abdominal muscles on the right side were rigid and a smooth tumour which seemed to move away from the examining hand could be felt. On the next morning the tenderness and rigidity had so much increased that the tumour could not be palpated. The leucocytes were 37,600 per cubic millimetre. Immediate operation was decided on. When the abdominal muscles relaxed under the anæsthetic it was easy to diagnose a distended gall-bladder. An incision was made over it. When the abdomen was opened some free fluid escaped. The gall-bladder was covered by adherent omentum. When this was removed the gall-bladder was found to be distended and its fundus of a dark purple colour. A number of abdominal pads were inserted, the gall-bladder was incised, and very foul pus was evacuated. The mucous membrane was green and gangrenous throughout. A large calculus was fixed at the mouth of the cystic duct. The fundus was gangrenous throughout all its coats and between it and the rest of the gall-bladder was a clear line of demarcation. The fundal portion was thin but the rest of the organ was much thickened, measuring from half an inch to one inch in thickness. It was decided to remove the gall-bladder. Its separation from the liver was easily accomplished with the finger, the tissues being soft from infiltration. When an attempt was made to ligature the cystic duct the gall-bladder separated and came away even before the first knot was tied. The cystic artery bled freely and could not be controlled by a pressure forceps as the instrument cut through the inflamed tissues. The hæmorrhage was arrested by gauze packing. Gauze drains were inserted and the wound was partially closed. The patient was very ill after the operation but on the next day she was better. Convalescence was uninterrupted and the wound healed rapidly. The leucocyte count on the morning of operation was 37,600; on the next day it had dropped to 12,600. Gangrenous cholecystitis probably depends on two factors—obstruction of the cystic duct and infection by virulent microbes; whether either alone can produce it cannot be said, since in all cases microbes and some obstruction, if only that from swollen mucous membrane, are present. Of course gangrene does not take place until the circulation is obstructed. Gangrenous cholecystitis is analogous to the much more common gangrenous appendicitis. The gangrene in the present case depended on impaction of the calculus cutting off the circulation. The symptoms are those of acute localised peritonitis. Jaundice is generally absent, unless there is marked cholangitis or the inflammation has extended to the liver. Gangrenous cholecystitis is liable to be mistaken for appendicitis, but under anæsthesia the two conditions can usually be differentiated. In both cases immediate operation is indicated and a gangrenous gall-bladder, like a gangrenous appendix, should be excised. Dr. Gibbon agrees with the advice of Mayo that the cystic duct should not be ligatured and is glad that his attempt to ligature it failed, for there is always some cholangitis which will be relieved by drainage.

THE HATCHING OF CHICKENS FROM EGGS TWELVE MONTHS OLD.

We have more than once directed the attention of our readers to the remarkable preserving properties of soluble glass or silicate of soda and it is surprising that this solution is not used more generally for the preservation of eggs. It is confidently stated that a newly laid egg will keep for many months when completely immersed in a 10 per cent. solution of the silicate and will then be indistinguishable as regards appearance and taste from an absolutely fresh egg. It shows the flakiness of the fresh egg and there are no signs of staleness whatever or of any disagreeable property which commonly characterises the "shop 'un." We have ventured to give an explanation of this remarkable preserving effect by assuming that the soluble silicate forms a hard, glassy, impermeable mass with the lime salts in the substance of the shell, a real insoluble glass, so that the contents are literally hermetically sealed against external influences. That is a remarkable enough fact, but it is now reported that chickens have been hatched from eggs preserved for 12 months in this way. This extraordinary result shows that not only are chemical changes prevented but that also the conditions of the vital processes in the egg remain unimpaired. The chicken thus hatched from a twelve-month-old egg is reported to be a quite strong and attractive bird. The recently reported success of this method, by which life would appear to be suspended so to speak, would seem to open up many possibilities in regard to the transportation and supply of food.

THE JOHNSTON LABORATORIES AT UNIVERSITY COLLEGE, LIVERPOOL.

The account given by our correspondent which appears at p. 1412 of the opening of the Johnston laboratories at University College, Liverpool, is of special interest inasmuch as the opening ceremony was performed by a Minister and that Minister the one who holds the very important post of President of the Local Government Board—namely, the Right Hon. Mr. Walter Long, M.P. We do not for one moment think that Mr. Long's presence pledged his colleagues in the Government to any course of action but we cannot help hoping that the fact is of good omen for a forthcoming Act which shall deal with the question of revaccination. Mr. Long, it will be seen by a reference to his speech, confessed that the object of his department was to impose regulations for restricting the spread of disease whilst interfering as little as possible with trade. Now, no one can say that vaccination interferes with trade. Meantime, we heartily congratulate Liverpool upon such a worthy citizen as Mr. William Johnston. Of old time the merchant princes of Europe gave funds or left moneys to drain fens or to build dykes or to found hospitals or religious houses for the purpose of looking after the sick and the needy. Bio-chemistry may not seem such a practical work but it is nevertheless no less valuable for the prevention of disease and the improving of the health of the people.

PUBLIC SUPPLIES OF MILK FOR INFANTS.

Medical men who practise in working-class districts are well aware that when mothers do not suckle their infants they have very vague ideas as to the selection and preparation of cow's milk or other substitutes for breast milk. In some large towns the difficulty has been partly met by some public body undertaking the supply of sterilised or sterilised and "humanised" milk for infants. This system was introduced, for instance, in St Helens, Lancashire, some years ago. A letter which appears on p. 1402 of our present issue is encouraging to the philanthropists who are in favour of this innovation, as it shows that the Royal Hospital for Children and Women in Waterloo Bridge-road is promoting a petition in this sense to the borough council of Lambeth. We understand that Battersea is the only metropolitan borough which has up to the present time undertaken this duty. Like most other questions, that of the public supply of milk for infants has two sides and an abstract of a paper on the subject read before the International Congress of Medicine at Madrid by Dr. A. L. Peyreux of Paris will be found on p. 1410 of our present issue. This gentleman disapproves of the indiscriminate supply of milk in this way on the ground that it tends to discourage the breast-feeding of infants.

VACCINATION, REVACCINATION, AND THE ADMINISTRATION OF THE VACCINATION ACT.

In view of the lapse at the end of the present year of the Vaccination Act now in force the medical officer of health of Huddersfield, Dr. S G. Moore, pursuant to a resolution of his health committee, attended a meeting of the Incorporated Society of Medical Officers of Health held in London on Feb. 11th, where the above subjects were discussed. At the meeting of the Huddersfield health committee held on March 25th a communication dealing with the same matters was received from the Royal Institute of Public Health and was referred to the medical officer of health for report. Dr. Moore has now submitted a memorandum to the health committee in which, shortly to summarise, he suggests, firstly, that the administration of the Vaccination Acts should be taken out of the hands of the Poor-law authorities; secondly, that vaccine lymph other than that supplied by the Local Government Board should be prepared and distributed under the supervision of local sanitary authorities; and, thirdly, that provision should be made for revaccination both general at the age of ten or 12 years, and special—i.e., in the case of persons recently exposed to infection; this last at least to be compulsory. Dr. Moore concludes by stating that the present is an opportune time to impress on the Government the necessity for improving the measures available against small-pox. He hopes that his recommendations will be received by the committee and the council and will be transmitted to the Local Government Board as representing the views of the latter. Further he requests the committee to take into consideration the advisability of securing the coöperation of other towns in the north of England. Dr. Moore's recommendations are good, but the Government has already played the medical profession false as regards revaccination, and we doubt whether polite resolutions from one or 50 town councils will weigh with the Government so much as a few words from General Phelps or Mr. Broadhurst Mr. Walter Long, however, is a Minister from whom much may be expected and if he will only take up the firm attitude upon vaccination which he took upon hydrophobia all may yet go well.

GUY'S HOSPITAL.

THE report of Guy's Hospital for the year 1902 states that on Dec. 31st of that year there were urgently required £85,000 to complete the renovation and building fund and to provide additional income for the purposes of maintenance. Moreover, the medical school requires for the "endowment of medical education and research," the sum of £125,000. The total income arising from investments is in round numbers £32,370 and the total expenditure in the same way is £90,720. The difference between these two sums is made up by grants from King Edward's Hospital Fund, the Sunday and Saturday Hospital Funds, and by transfers from the sustentation fund and from capital account. Elsewhere we have recorded the fact that another great metropolitan hospital is about to appeal for funds. Guy's Hospital for 160 years performed a great public work without public aid. St. Bartholomew's Hospital has done the same thing for 780 years. Both hospitals have a noble record and both, it is certain, will make a good use of whatever moneys they may procure, but even the purse of charity is not bottomless and the risk that other and more needy institutions may be injured by the answer to the appeals from Guy's and from St. Bartholomew's Hospitals has to be faced.

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

THE American Electro-Therapeutic Association has issued its report for the year 1902–03, which is prefaced by an interesting historical sketch of the inception and progress of the society. It was founded in 1891 and the first annual meeting was held at Philadelphia. The association would appear to be doing good work in the reading of papers and in the appointment of standing committees on various forms of electric and electro-therapeutic apparatus. Electro-therapeutics have been so exploited by quacks and swindlers that we are always glad to see this branch of medicine dealt with by a scientific society. We do not see any mention in the by-laws or other regulations of the society that it concerns itself with the doings of quacks, an omission which we hope will be rectified in future, for we have no doubt that if strong protests were to be made to the authorities by duly authorised representatives of the profession the dens of thieves who sell "magnetic invigorators" and the like would be weeded out. We are quite aware that we in this country are by no means blameless or free from these pests and possibly the time will come when the medical profession on both sides of the Atlantic will unite in doing its utmost to put down one at least of the many forms of quackery which rob the pockets and sap the health of their victims.

THE DISTRIBUTION OF PLAGUE.

As regards the Cape Colony the acting medical officer of health states that for the week ending April 18th the condition of the various places mentioned below was as follows:—At the quarantine station, Saldanha Bay, 2 Asiatic males remained under treatment in the hospital, both being convalescent. At Port Elizabeth 7 cases of plague were discovered—namely, 1 native male, on April 12th; 1 native male (found dead) on the 13th; 2 native males (1 of whom was found dead) and 1 native female on the 15th; 1 European male and 1 native male (found dead) on the 18th. At the plague hospital, Port Elizabeth, 1 coloured male and 1 native male died during the week, while 1 coloured female was discharged cured, leaving 17 cases under treatment. Plague-infected rats continued to be found in the town during the week. At East London on April 14th a native male was admitted to hospital suffering from plague and died on the 17th. 1 native male was discharged cured during the week, leaving 1 case under treatment at the plague hospital. Plague-infected rats continued to be found in the town during the week. At King William's Town 2 cases of plague were discovered—namely, 1 native male (found dead) on April 16th, and 1 native male (found dead) on the 18th. At the plague hospital 1 European male died and 2 European males were discharged cured, leaving 1 patient under treatment No cases of plague and no plague-infected rats were found in Graaff-Reinet during the week. As regards the Mauritius a telegram from the Governor received at the Colonial Office on May 8th states that for the week ending May 7th there was 1 fatal case of plague.

MYOPIA IN DIABETES MELLITUS.

IT was first demonstrated by Hirschberg that in the course of diabetes mellitus some degree of myopia occasionally develops in eyes previously emmetropic or hypermetropic, without turbidity of the lens or cataract. Dr. Sigmund Neuburger of Nuremberg in the *Munchener Medicinische Wochenschrift*, No. 12, 1903, records two examples of this diabetic myopia which he had an opportunity of observing. and in both of which the ocular condition led to the discovery of the diabetes. The patients were women, aged about 50 years, whom Dr. Neuburger had known previously to the development of the myopia, one having been emmetropic and the other slightly hypermetropic. In the first case the myopia soon passed off and no other ocular signs developed except slight change in the macular region of the right eye, although the other diabetic symptoms increased. In the second case, on the other hand, the myopia increased, reaching a degree of – 8 D., and at a later period diabetic cataract developed. The explanation given of this change is that it is due to an alteration in the refractive index of the lens substance induced by the diabetes. This explanation, however, seems hardly convincing as it is difficult to see, on the one hand, why the change is not more common if it depends upon the altered condition of the circulating fluids in diabetes, and, on the other, why the condition can pass off while the diabetic changes elsewhere are increasing. It may, however, be of importance in the early diagnosis of diabetes by leading to an examination of the urine for sugar, which, according to Dr. Neuburger, should be done in all cases of myopia beginning in middle age.

ANTHROPOMETRICS IN SALFORD.

IN THE LANCET of March 28th, p. 926, attention was drawn to an interesting and important inquiry that was being carried out in three of the Salford board schools as to the physical characteristics of the boys at various ages. It was decided at the meeting of the school board held on April 27th that the subcommittee in charge of the matter should be authorised to take anthropometric measurements of boys at the ages of eight, ten, and 13 years in *all* the boys' and mixed departments of the board schools. This decision is satisfactory, for though measuring the boys will not of itself do much to improve their physique it is well that the facts should be known. If no interest is felt as to whether our urban lads grow up weakly or strong no attempts will be made to improve the conditions under which they live. It may be remembered that the Grecian-street school stood well as compared with one in Pendleton, but it appears from the returns that the Grecian-street boy is a little less in height and in weight than the London board school boy and three inches less in height than the average public school boy of his age and nine pounds less in weight. Taking the John-street school type—the worst of the three—the boy aged 13 years was seven inches shorter and 25 pounds less in weight than the public school boy. "The Salford boy, he thought," said the Rev. Mr. Rees, "was physically punier than other boys and rivalled the boy of Rochdale." This statement is not encouraging for Salford and still less so for Rochdale. It is a national calamity that so large a proportion of our population are growing up puny weaklings and the result may some day be disastrous. The contrast would be pitiful if these town-dwellers were put side by side with some of the well-grown and magnificently proportioned men and women to be seen on the Lancashire Fells.

TUBERCULOUS PERICARDITIS.

TUBERCULOSIS of the pericardium is a rare condition though it is probable that it is sometimes not recognised even at a post-mortem examination when the pericardial adhesions present are thought to be due to some other cause. Dr. Osler has given in the *American Journal of the Medical Sciences* a clinical classification of cases of the disease. He divides them into four groups. In the first the disease shows no distinctive sign and the condition is only found at the necropsy. This occurs chiefly in cases where the pericarditis is secondary to tuberculosis of the lungs. In the second class are cases in which the adherent pericardium present gives rise to symptoms of cardiac embarrassment; in the third group are cases with evidence of pericardial effusion, but the cause of the effusion may be unsuspected, and in the last group are cases of acute general tuberculosis, and the pericardium only suffers with many other organs. Primary tuberculous pericarditis is much less common than the secondary form, which chiefly results as an extension from tuberculosis of the lungs or it may occur in an acute form as the result of the bursting of a caseating bronchial gland. In the present issue of THE LANCET is an account by Dr. J. Odery Symes of Bristol of an interesting case of tuberculous pericarditis occurring secondarily to disease of the lung; there was much pericardial effusion and repeated aspiration was necessary. The tuberculous nature of the pericarditis was made certain by the presence of tubercle bacilli in the fluid.

THE King has sanctioned the following appointments to the Order of the Hospital of St. John of Jerusalem of England: Sir Arthur Conan Doyle, Lieutenant-Colonel Edmond Munkhouse Wilson, C.B., C.M.G., D.S.O., R.A.M.C., Surgeon-General Alfred Keogh, C.B., and Lieutenant-Colonel William Babtie, C.M.G., V.C., R.A.M.C., to be Knights of Grace.

THE Ingleby Lectures of the University of Birmingham will be delivered in the medical lecture theatre of the university on Tuesdays, June 9th and 16th, at 4 P.M. The Ingleby lecturer for the year is Mr. William F. Haslam, F.R.C.S. Eng., surgeon to the General Hospital, Birmingham, and the subject of his lectures will be "The Surgery of the Pancreas."

THE dinner of the Sanitary Institute will be held in the Richelieu and Medici Rooms at the Hotel Cecil, London, on Friday, May 15th, at 7.30 P.M., when H.R.H. the Duke of Cambridge, K.G., the President of the institute, will take the chair.

A RECEPTION by their Royal Highnesses the Prince and Princess of Wales, Grand President and Lady Grand President of the League of Mercy, will be held in connexion with the League at Marlborough House on May 22nd.

THE next session of the General Council of Medical Education and Registration will begin on May 21st at 2 P.M., Sir William Turner, K.C.B., the President, being in the chair.

THE annual banquet of the Coroners' Society of England and Wales will be held at the Holborn Restaurant, London, on Thursday, May 28th, at 6.30 for 6.45 P.M.

THE MEDICAL PROFESSION AND THE MERCANTILE MARINE.

Paterson v. the Peninsular and Oriental Steam Navigation Company.

IN July, 1902, Dr. T. W. S. Paterson agreed with the Peninsular and Oriental Steam Navigation Company in London to go as surgeon on one of its steamers from London for one voyage out and home. The ship to which he was appointed was the *Socotra* sailing to Japan. On joining the ship he was requested to sign the ship's articles as prescribed by the Board of Trade. Pasted on to the articles was a printed strip which contained two by-laws of the company. One of the by-laws was worded as follows:—

> That the crew or any member thereof may be transferred if required at any port, at any time, to any other vessel of the company, wages, capacity, and terms of service being the same.

Dr. Paterson took exception to this clause and at first refused to sign the articles, but on being verbally assured that this by-law would not be acted on he signed the articles and joined the ship He was described in the articles as "seaman." By the merchant shipping law a surgeon is considered an ordinary seaman. Upon arriving at Shanghai on the homeward voyage on Oct. 19th, 1902, Dr. Paterson was ordered by the company's agent through the captain to transfer himself to the s.s. *Ballarat*, one of the company's ships plying between Bombay and Shanghai and not going home. He refused to do this. The agent then instructed the captain of the *Socotra* to prosecute the surgeon of the *Socotra* for refusal to obey the lawful orders of the captain. A summons was accordingly issued for the surgeon to appear at H.B.M.'s Police-court, Shanghai, in that he did on Oct. 21st, 1902, refuse to obey the lawful command of the captain of the s.s. *Socotra*. Dr. Paterson tried to obtain legal assistance in Shanghai but failed owing to want of ready money. Fortunately there was a copy of the Merchant Shipping Act of 1894 on board.

On being arraigned before the magistrate the defendant inquired whether he was charged with a civil or a criminal offence. The magistrate replied that "the offence was one in respect of which defendant was liable to imprisonment without hard labour for a term not exceeding four weeks, or in the discretion of the court to a fine not exceeding two days' pay. It was a criminal offence." The defendant, while admitting that he refused to obey the captain's orders, denied that the order was a lawful one and quoted Section 187 of the Act of 1894 which says: "A captain shall not leave or cause to be left behind a seaman in a foreign port." He further pleaded that the by-laws in question were extraneous matter pasted on the articles and quoted Section 122 of the Merchant Shipping Act which says that "the consent of the whole crew must be obtained to any alteration in the ship's articles." He denied that the company had his consent. Finally, if he did sign them, he signed them under protest and had a verbal promise releasing him from this clause in the articles, evidence of which would be forthcoming. The magistrate did not decide the case on the point of fact as to whether or not the defendant had this verbal promise, but on a point of law as to whether the by-laws of the company could override the articles prescribed by the Merchant Shipping Act. He decided that the by-laws could not do so, were in law *ultra vires*, and dismissed the charge.

The *Socotra* left Shanghai for Manilla on the homeward voyage on Oct. 25th. Just before leaving Dr. Paterson was informed by the company's solicitors in Shanghai that the company would appeal from the police-magistrate's decision. Dr. Paterson then instructed a firm of solicitors at Shanghai who on receiving suitable references undertook to represent him; at the same time he instructed his solicitors in London to do all in their power to stop the appeal, with its attendant risks of a criminal conviction. Mr. F. S. A. Bourne, acting Chief Justice of the Supreme Court of North China and Korea, dismissed the appeal with costs. The company then applied for permission to appeal to H.M. Privy Council in London. His lordship granted permission to appeal on condition that the company paid all the costs of the appeal to the Privy Council, including a sum not exceeding £150 for the costs of the respondent in London. On arriving in London in December, 1902, Dr. Paterson found that his solicitors had demanded an apology from the company on his behalf, the cessation of the prosecution in Shanghai, and such costs as he had then incurred. This demand not being complied with and learning by cable that the company had asked for leave to appeal to the Privy Council, Dr. Paterson instructed his solicitors in London to proceed with an action in the High Court, London, against the company, claiming damages for malicious prosecution.

The company filed its defence to this action on Feb. 26th, 1903. It is as follows:—1. The defendant company did not prefer any complaint as alleged. 2. If any complaint was preferred in the name of the defendants the same was preferred without the authority of the defendants. 3. The complaint referred to was not preferred maliciously or without reasonable and probable cause. 4 The defendant company did not serve any such notice of appeal as is referred to. 5. If any such notice of appeal was served it was not served with the authority of the company. 6. Such notice of appeal was not given maliciously or without reasonable or probable cause. 7. The defendants will object that the plaintiff cannot recover in respect of grievances happening or special damage accruing after the commencement of this action. 8. The defendants, while denying liability, bring into court the sum of £555 and say that it is sufficient to satisfy the plaintiff's claim.

In March, 1903, this sum was taken out of court by the plaintiff and so the action has terminated without a public hearing in court, the company paying also the plaintiff's taxed costs of the action.

METROPOLITAN HOSPITAL SUNDAY FUND.

AT a meeting of the council of the Metropolitan Hospital Sunday Fund, which was held at the Mansion House on May 12th under the presidency of the Lord Mayor, a vote of condolence with the family of the late Prebendary Kitto was passed on the motion of the Rev. F. C. Carr Gomm, seconded by Mr. J. H. Hale.

Among those present were Sir Joseph Dimsdale, the Bishop of Stepney, Archdeacon Sinclair, Mr. Wakley, Prebendary Ridgeway, and Canon Rhodes Bristow.

The Lord Mayor announced that, by the King's desire, the Hospital Sunday collection would be taken at St. Paul's Cathedral on Sunday, June 7th. The collections at other places of worship would be made on June 14th. Mr. George Herring, the Lord Mayor said, had again offered to contribute £25,000 provided that £100,000 were raised in the various places of worship. He (the Lord Mayor) would attend the service at St. Paul's Cathedral on June 7th and it would give him the greatest pleasure to receive contributions from anyone who desired to commemorate the visit of their Majesties on such a historic occasion—the first on which the Sovereign had attended St. Paul's Cathedral for the express purpose of benefiting the London hospitals. The whole deficiency of the London hospitals, provided that they were kept under the control of this and similar funds, amounted to £250,000 per annum. This meant that if the Hospital Sunday Fund could raise £100,000 yearly, King Edward's Fund £100,000, and the Hospital Saturday Fund £50,000, assistance from the rates would not be required. Banks, insurance companies, and most of the limited liability companies were entitled to contribute out of their corporate funds towards hospital purposes, and since this fact had been made known nearly every bank in the City had sent him a donation towards the London Hospital. If the banks and the limited liability companies generally could make up their mind to contribute towards one of the three funds for assisting the hospitals the deficiency of £250,000 would soon be made up. According to his promise made at the conference of ministers which was recently held at the Mansion House he had sent out 5000 letters of appeal to the principal residents in the home counties. The King and Queen had consented to attend the service at St. Paul's Cathedral on June 7th and this fact should insure a record collection.

Sir Edmund Hay Currie read the following letter from Mr. George Herring:—

> I propose to make the same offer as last year to the council of the Hospital Sunday Fund—namely, I will send a cheque for £10,000, or add one-fourth to the amount collected in all places of public worship. But you are showing such increased energy this year that I must limit the amount to £100,000, so that if the collection exceeds that sum (which I sincerely hope may be the case) I only give £25,000.

Sir Henry Burdett said that limited liability companies had now taken the place of private firms to a large extent and if the former would only contribute a due proportion of their profits to charities, as was formerly done by the heads of private business houses, the London hospitals would soon be in a sound financial position.

Archdeacon Sinclair said that Sir Edmund Hay Currie was endeavouring to obtain the consent of a number of gentlemen to act as stewards at the service at St. Paul's Cathedral on June 7th. Mr. William Herring had offered to act as a steward and promised to head his list with £1000.

The Bishop of Stepney said that the King wished his visit to the Cathedral to be as far as possible of a personal and private character and the object of his presence at the service was to support the Metropolitan Hospital Sunday Fund in the effort which was being made to increase the amount collected. Their business must be to coöperate with the King in making the service at the Cathedral an opportunity for awakening latent interest in the hospitals.

Prebendary Ridgeway said that, while desiring to get a large collection at St. Paul's Cathedral, he hoped they would avoid drawing on the congregational collections throughout London. The service at St. Paul's Cathedral was to increase the general interest in the Hospital Fund on the following Sunday.

Archdeacon Sinclair said that the object of the service at St. Paul's Cathedral was to reach only those connected with the City and not to appeal to wealthy people outside. The Bishop of Stepney would probably preach the sermon.

On the motion of Dr. J. G Glover a vote of thanks to the Lord Mayor terminated the proceedings.

THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A QUARTERLY meeting of this College was held on May 5th, Dr. T. S. Clouston, the President, being in the chair.

The President read the following loyal address which had been prepared for presentation to King Edward on his approaching visit to Edinburgh and which was unanimously approved:—

To the King's Most Excellent Majesty.

The humble, loyal, and dutiful address of the President and Fellows of the Royal College of Physicians of Edinburgh. May it please your Majesty,

We, your Majesty's loyal and dutiful subjects, the President and Fellows of the Royal College of Physicians of Edinburgh, desire to offer your Majesty our most hearty welcome on your Majesty's visit to the capital of Scotland. We desire also to thank your Majesty for the honour you have thus conferred on Edinburgh and we earnestly hope your Majesty's stay here will be a pleasure to your Majesty and to Queen Alexandra

We know the great interest your Majesty has always taken in the profession of medicine and in all those institutions whose object is to cure disease and to mitigate human suffering. This being the work of the Fellows of our College, none of your Majesty's subjects are better able than they to realise the great benefits that have resulted to the sick and to the progress of medicine through your Majesty's example and influence in supporting hospitals, in promoting the public health, and in encouraging the medical profession in its increasing fight against disease. Your Majesty's ancient capital of Scotland stands out in your Majesty's whole realm as a mother city of noble hospitals and great medical corporations and is the seat of the largest medical school in your Majesty's dominions. The College therefore specially appreciates your Majesty's sympathy with medical objects and your Majesty's patronage of medical institutions.

That the Almighty may grant to your Majesty and to your Royal house the blessings of health and happiness is the fervent prayer of your Majesty's most loyal and faithful servants.

The President referred in sympathetic terms to the loss which the College had sustained through the death of Mr. J. Matheson Shaw, the late sub-librarian.

The following Members were admitted by ballot to the Fellowship of the College: Henry Aylmer Dumat, M.D. Edin.; William Thomas Ritchie, M.D. Edin.; John Cumming, F.R.C.S.Edin.; and Alexander Dingwall Fordyce, M.B., Ch.B. Edin.

The Registrar reported that since the last quarterly meeting 52 persons had obtained the Licence of the College by examination.

The Curator's report regarding the work undertaken in the laboratory during the past year showed that 29 workers had been engaged in research, that 1868 specimens had been reported on, and that the expenditure had amounted to £1017.

The Freeland-Barbour Fellowship was awarded to Dr. Alexander Goodall of Edinburgh.

The Treasurer announced that the late Mr. J. Matheson Shaw, sub-librarian of the College, had bequeathed a sum of money for the purpose of founding a lectureship in the College, the lectures to treat of recent advances in medicine.

The draft regulations regarding the various examinations for the triple qualification for the ensuing year were considered and approved.

By vote of the College John Flanagan was suspended *sine die* from his Licence to practise, as granted by the College, and from all his rights and privileges as Licentiate.—Alfred Hunter Goodwyn was expelled from the College and deprived of his Licence to practise, as granted by the College, and of all his rights and privileges as Licentiate.

Looking Back.

FROM

THE LANCET, *SATURDAY*, MAY 14, 1825.

REGULAR PHYSICIANS GRINDING ![1]

Surely, Mr. Editor, were it not a grave subject, one might laugh to think, that a young man just passed his minority might, by *a mechanical process*, get up a thesis, and grind himself into an M.D., whilst a man of the most extensive education and long practice, who has been educated in London rather than in Edinburgh, and who has legally obtained a degree from Aberdeen, instead of Edinburgh or Glasgow, is to be regarded as an irregularly educated physician. The expense of a medical education is here out of the question, it being well known that the fees of attendance, and living in London are greater; and that the graduating fee at either of the Universities of the North, is about *the same,—viz. nearer 30l. than 15l.*, as mentioned by Mr. Brougham in the House.

We have heard much of late of the degenerated state of the medical profession. How is this to be accounted for? Are not as many regularly ground M.D.'s thrown off annually on the world as heretofore? If the latter question be answered affirmatively, will this explain the cause? Or is it owing to the before-named mal-practices of the more northern Universities? In truth I am not inclined to think that the profession is more degenerate, I *most heartily* concur in the sentiment of Sir ASTLEY COOPER on this subject, who says, "it is consolatory to know that the human frame is better understood at the present epoch by *students*, than it was forty years ago by *professors*. The march of improvement has been most rapid."* I much suspect, Sir, that the croaking has originated with the would-be-lights of the world, and that the unnatural efforts which have been made to protect favoured schools, and self-favouring partizans, have tended much to bring the odium which exists, if there be any, on the profession. I regret the withdrawment of Sir ASTLEY COOPER from the Borough School; he retires, however, full of honours. Let us hope that men will be found with equal zeal for the education of our medical students, to follow up those principles which he, during many years, so ably inculcated.

Admitting for a moment, and that for argument sake only, that a man who has graduated at Edinburgh, after grinding, is the most regularly educated, and that it is a desideratum that all who practise as physicians should, in the first place, grind *secundum artem*. Why not establish a university in London, for the purposes of college education, and for the conferring of degrees? The consequence of such a measure would be, that few of our English students would then go to the north at all, except on the score of saving expence. If, however, we cannot have an university in the British metropolis, where medical students may graduate, let the pupils of the first medical schools be allowed to enter any one of the Scotch *Universities, and let them be received as candidates for the doctorate*, which should be granted to them as the result of successful examination in *real attainments*. Let them be examined in every branch connected with the profession, wherever they may have studied. It is a mere farce to pretend that a man cannot be regularly educated as a medical practitioner in England or in Scotland, and it is worse than a farce to presume that a man is qualified to preside in a consultation with his medical brethren because he has been drilled for a few months to the answering of questions on medical science in Scotch Latin.

---

* Lancet, vol. i., p. 6.

[1] Excerpts from a letter to the Editor of THE LANCET, signed "R. H. F."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8608 births and 4618 deaths were registered during the week ending May 9th. The annual rate of mortality in these towns, which had been 15·9, 17·4, and 17·5 per 1000 in the three preceding weeks, declined again last week to 16·0 per 1000. In London the death-rate was 15·7 per 1000, while in the 75 other large towns it averaged 16·1 per 1000. The lowest death-rates in these towns were 8·2 in Willesden, 10·2 in Leyton and in Hastings, 10·3 in Croydon, 10·6 in Kings Norton, 11·0 in Derby, 11·1 in Hull, and 11·2 in Brighton and in Cardiff; while the highest rates were 19.7 in Rochdale, 20·1 in Great Yarmouth, 20·8 in South Shields and in Tynemouth, 20 9 in Liverpool, 21·0 in Oldham, 22·5 in Middlesbrough, and 23·5 in Wigan. The 4618 deaths in these towns last week included 457 which were referred to the principal infectious diseases, against 454, 504, and 518 in the three preceding weeks; of these 457 deaths 137 resulted from measles, 124 from whooping-cough, 57 from diarrhœa, 50 from diphtheria, 48 from scarlet fever, 27 from "fever" (principally enteric), and 14 from small-pox. In Brighton, Reading, Norwich, Plymouth, Devonport, York, Newport (Mon.), and in seven other smaller towns, no death from any of the principal infectious diseases was registered last week; the highest death-rates from these diseases were recorded in Tottenham, Walthamstow, Wolverhampton, West Bromwich, Bootle, Wigan, Oldham, Sheffield, and Rhondda. The greatest proportional mortality [illegible] Walthamstow, [illegible]; from whooping-[illegible] West Bromwich, Coventry, Oldham, Huddersfield, Sheffield, and Rhondda: from "fever" in Bootle, and from diarrhœa in Wallasey. The mortality from scarlet fever and from diphtheria showed no marked excess in any of the large towns. Four fatal cases of small-pox were registered in Liverpool, two in Walsall, two in Leicester, and one each in Bury, Manchester, Rochdale, Bradford, Leeds, and Sheffield. The Metropolitan Asylums hospitals contained 60 small-pox patients on Saturday last, May 9th, against numbers increasing from five to 47 on the ten preceding Saturdays; 17 new cases were admitted during the [illegible] weeks. [illegible] and in [illegible] .00, and 1717 at the end of the three preceding weeks, had further risen to 1730 at the end of last week; 229 new cases were admitted during the week, against 188, 243, and 235 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 262, 280, and 284 in the three preceding weeks, declined again last week to 260, but were 20 above the number in the corresponding period of last year. The causes of 57, or 1·2 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner. The causes of all the deaths were duly certified in Portsmouth, Bristol, Nottingham, Salford, Bolton, Leeds, Cardiff, and in 46 other smaller towns; the largest proportions of uncertified deaths were registered in Smethwick, Liverpool, Bootle, Wigan, Blackburn, Sheffield, and Middlesbrough.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 17·7, 18·5, and 19·2 per 1000 in the three preceding weeks, declined again to 17·9 per 1000 during the week ending May 9th, but was 1·9 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 11·5 in Dundee and 14·9 in Aberdeen to 20·1 in Perth and 24·8 in Greenock The 585 deaths in these towns included 26 which were referred to whooping-cough, 11 to diarrhœa, eight to measles, five to diphtheria, four to scarlet fever, and three to "fever," but not one to small-pox. In all, 57 deaths resulted from these principal infectious diseases last week, against 53, 59, and 57 in the three preceding weeks. These 57 deaths were equal to an annual rate of 1·7 per 1000, which was slightly above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 17, 30, and 32 in the three preceding weeks, declined again last week to 26, of which 14 were registered in Glasgow, four in Edinburgh, and two in Leith. The deaths from diarrhœa, which had been 17, 18, and 11 in the three preceding weeks, were again 11 last week, and included three in Glasgow, three in Dundee, and three in Aberdeen. The fatal cases of measles, which had been seven, four, and seven in the three preceding weeks, rose last week to eight, of which five occurred in Edinburgh and two in Glasgow. The deaths from diphtheria, which had been eight, two, and one in the three preceding weeks, increased again to five last week and included two in Glasgow and two in Edinburgh. The fatal cases of scarlet fever, which had been two, two, and four in the three preceding weeks, were again four last week; of these, two were recorded in Glasgow and two in Paisley. Two of the fatal cases of "fever" occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 109, 129, and 125 in the three preceding weeks, further declined last week to 104 and were slightly below the number in the corresponding period of last year. The causes of 21, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·5, 24·8, and 25 7 per 1000 in the three preceding weeks, declined again to 25·3 per 1000 during the week ending May 9th. During the past four weeks the death-rate has averaged 25·1 per 1000, the rates during the same period being 16·5 in London and 17·5 in Edinburgh. The 184 deaths of persons belonging to Dublin registered during the week under notice showed a decline of three from the number in the preceding week and included 15 which were referred to the principal infectious diseases, against six, eight, and nine in the three preceding weeks; of these, four resulted from small-pox, four from whooping-cough, three from "fever," two from scarlet fever, one from diphtheria, and one from diarrhœa, but not one from measles. These 15 deaths were equal to an annual rate of 2·1 per 1000, the death-rates last week from the same diseases being 1·7 in London and 2·1 in Edinburgh. The fatal cases of small-pox numbered four last week against three in the previous week. The deaths from whooping-cough, which had been one in each of the three preceding weeks, rose last week to four. The fatal cases of "fever," which had been two, one, and two in the three preceding weeks, increased to three last week. The 184 deaths in Dublin last week included 32 of children under one year of age and 46 of persons aged 60 years and upwards; the deaths of infants slightly exceeded the numbers in the preceding week, while those of elderly persons showed a marked decline. Five inquest cases and two deaths from violence were registered, and 62, or more than a third, of the deaths occurred in public institutions. The causes of ten, or more than 5 per cent., of the deaths in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING APRIL, 1903

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 5·4 per 1000 of the population, estimated at 4,613,812 persons in the middle of the year. In the three preceding months the rates had been 6·5, 6·2, and 5·9 per 1000 respectively. The rates were considerably below the average in Hammersmith, the City of Westminster, Hampstead, Stoke Newington, the City of London, Bethnal Green, and Greenwich, while they showed the largest excess in Chelsea, St. Marylebone, Bermondsey, Wandsworth, Deptford, Lewisham, and Woolwich. The prevalence of small-pox showed a marked increase upon that recorded in the preceding month; of the 48 cases notified during April, seven belonged to Poplar, seven to Southwark, five each to Kensington, Fulham, and Camberwell, and four to Battersea. The Metropolitan Asylums hospitals contained 47 small-pox patients at the end of last month, against seven, five, and 13 at the end of the three preceding months; the weekly admissions averaged 12, having been three in each of the six preceding months. The prevalence of scarlet fever showed a slight decline last month as compared with the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in Chelsea, St. Marylebone, Wandsworth, Deptford, Lewisham, and Woolwich. The number of scarlet fever patients in the Metropolitan Asylums hospitals, which had been 1980, 1820, and 1704 at the end of the three preceding months, had further declined to 1685 at the end of last month; the weekly admissions averaged 201, against 212, 205, and 208 in the three preceding months. The prevalence of diphtheria last month was slightly less than in the preceding month; this disease was proportionally most prevalent in Hackney, Shoreditch, Stepney, Poplar, Lewisham, and Deptford. There were 760 cases of diphtheria under treatment in the Metropolitan Asylums hospitals at the end of last month, against 936, 1030, and 903 at the end of the three preceding months; the weekly admissions averaged 105, against 131, 152, and 126 in the three preceding months. Enteric fever was much less prevalent during April than in any recent month; among the various metropolitan boroughs the greatest proportional prevalence of this disease occurred in the City of Westminster, St. Marylebone, Stoke Newington, Holborn, Southwark, Bermondsey, and Lambeth. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 172, 125, and 92 at the end of the three preceding months, had further declined to 53 at the end of the last month; the weekly admissions averaged five, against 22, 13, and 15 in the three preceding months 10 cases of typhus fever were notified during April, of which eight belonged to the borough of Bermondsey. Erysipelas was proportionally most prevalent in Kensington, Chelsea, St. Marylebone, Finsbury, Shoreditch, and Deptford. The 17 cases of puerperal fever notified during the month included three in Islington, three in Camberwell, two in the City of Westminster, and two in Hackney.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in public institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending May 2nd the deaths of 5596 persons belonging to London were registered, equal to an annual rate of 15·8 per 1000, against 18·2, 16·5, and 15·9 per 1000 in the three preceding months. The lowest death-rates in the several metropolitan boroughs last month were 10·4 in Hampstead, 11·7 in Wandsworth, 11·8 in Lewisham, 12·8 in the City of London and in Camberwell, and 13·2 in Greenwich; the highest rates were 18·1 in St. Marylebone, 18·2 in Southwark, 18·8 in Stepney and in Poplar, 19·1 in Finsbury, 21·9 in Shoreditch, and 22·1 in Holborn The 5596 deaths from all causes included 622 which were referred to the principal infectious diseases; of these, 270 resulted from measles, 23 from scarlet fever, 64 from diphtheria, 169 from whooping-cough, two from typhus fever, 17 from enteric fever, one from simple continued fever, and 76 from diarrhœa, but not one from small-pox. The lowest death-rates last month from these infectious diseases were recorded in Hammersmith, Fulham, St. Marylebone, Hampstead, Finsbury, Camberwell, and Woolwich; and the highest

* Including membranous croup.

rates in St. Pancras, Stoke Newington, Shoreditch, Bethnal Green, Stepney, Poplar, and Greenwich. The 270 deaths from measles were 13 below the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in St. Pancras, Stoke Newington, Holborn, Shoreditch, Bethnal Green, Stepney, and Poplar. The 23 fatal cases of scarlet fever showed a decline of 30 from the average number in the corresponding periods of the ten preceding years; the highest proportional mortality from this disease occurred in the City of Westminster, Hampstead, Hackney, and, Bermondsey. The 64 deaths from diphtheria were slightly less than one half of the corrected average number; among the various metropolitan boroughs this disease showed the highest proportional fatality in Stoke Newington, Shoreditch, Bethnal Green, Deptford, and Greenwich. The 169 fatal cases of whooping-cough were 76 below the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Paddington, Kensington, Islington, Stoke Newington, Poplar, and Battersea. The 20 deaths referred to different forms of "fever" showed a decline of eight from the corrected average number; among the various metropolitan boroughs the highest "fever" death-rates were recorded in Paddington, the City of Westminster, Lambeth, and Bermondsey, two fatal cases of typhus fever both belonging to the last-named borough. The 76 deaths from diarrhœa were 30 in excess of the average number in the corresponding periods of the ten preceding years; the highest proportional mortality from this disease occurred in Hammersmith, Fulham, Chelsea, Shoreditch, Stepney, Poplar, and Southwark. In conclusion, it may be stated that the aggregate mortality from these principal infectious diseases in London last month was more than 23 per cent. below the average.

Infant mortality in London during April, measured by the proportion of deaths among children under one year of age to registered births, was equal to 118 per 1000. The lowest rates of infant mortality were recorded in Hammersmith, the City of Westminster, Holborn, Wandsworth, Camberwell, Greenwich. and Lewisham; and the highest rates in Chelsea, Stoke Newington, Shoreditch, Poplar, Southwark, and Battersea.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointment is notified:—Staff Surgeon C. S. Woodwright to the *Victory* and tenders for instruction of Probationary Sick Berth Staff, to date May 18th.

ARMY MEDICAL STAFF.

Colonel W. J. Fawcett, from Royal Army Medical Corps, to be Surgeon-General, on temporary augmentation. Dated April 1st, 1903.

ROYAL ARMY MEDICAL CORPS.

Surgeon-Captain (temporary Surgeon-Lieutenant in the Army) H. N. A. Taylor, 3rd Volunteer Battalion the Essex Regiment, is granted the temporary rank of Surgeon-Captain in the Army whilst serving with the regular troops. Dated Feb. 7th, 1903

INDIAN MEDICAL SERVICE.

Bengal Establishment: Lieutenant-Colonels to be Colonels: Mathew Denis Moriarty (dated Oct. 25th, 1902) and Bartholomew O'Brien (dated Nov. 1st, 1902).

The King has approved of the retirement from the service of the undermentioned officers:—Lieutenant-Colonel Alfred James O'Hara (dated Nov. 2nd, 1902) and Lieutenant-Colonel Alfred William Frederick Street, D.S.O. (dated April 2nd, 1903).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major F. W. Grant having resigned his appointment in the Volunteers ceases to be an officer in the Army Medical Reserve of Officers. Dated May 9th, 1903. Surgeon-Lieutenant Robert Athelstan Draper, 1st East Riding of Yorkshire, Royal Garrison Artillery Volunteers, to be Surgeon-Lieutenant. Dated May 9th, 1903. Surgeon-Captain Thomas Kay, 1st Lanarkshire Royal Garrison Artillery Volunteers, to be Surgeon-Captain. Dated May 13th, 1903.

IMPERIAL YEOMANRY.

Royal North Devon (Hussars): William Francis Lucius Austen Holcroft to be Surgeon-Lieutenant under paragraph 30 Yeomanry Regulations. Dated May 9th, 1903. Glamorganshire: Surgeon-Lieutenant R. M. Moynan resigns his commission. Dated May 9th, 1903. 4th County of London (King's Colonials): Surgeon-Lieutenant L. J. H. Oldmeadow resigns his commission. Dated April 2nd, 1903.

VOLUNTEER CORPS.

Submarine Miners: The Tyne Division: Surgeon-Major F. W. Gibbon, from 1st Durham Royal Engineers (Volunteers), to be Surgeon-Major. Dated May 13th, 1903.

Rifle: 7th Volunteer Battalion the Royal Scots (Lothian Regiment): Surgeon-Lieutenant A. J. Grant to be Surgeon Captain. Dated May 13th, 1903. 1st Volunteer Battalion the Royal Fusiliers (City of London Regiment): Surgeon Lieutenant J. R. Ryan to be Surgeon-Captain. Dated April 28th, 1903. 3rd (Dundee Highland) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon-Captain W. Kinnear to be Surgeon-Major. Dated May 9th, 1903. Surgeon-Lieutenant. W. S. Malcolm to be Surgeon-Captain. Dated May 9th, 1903. 1st Volunteer Battalion the Norfolk Regiment: Surgeon-Lieutenant J. M. G. Bremner to be Supernumerary whilst serving with the Norfolk Volunteer Infantry Brigade Bearer Company. Dated March 14th, 1903 3rd Volunteer Battalion the Essex Regiment: The promotion of Surgeon-Lieutenant H. N. Taylor to the rank of Surgeon-Captain, which was announced in the *London Gazette* of Feb 6th last bears date Dec. 30th, 1902. 3rd (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Lieutenant W. D. Macfarlane to be Surgeon-Captain. Dated May 9th, 1903 3rd (Cambridgeshire) Volunteer Battalion the Suffolk Regiment: Surgeon-Captain E. L. Jones resigns his commission. Dated May 13th, 1903. 2nd (South) Middlesex: The undermentioned Surgeon-Lieutenants to be Surgeon-Captains:—E. P. Isaacs (dated April 21st, 1903) and S. F. Holloway (dated April 21st, 1903). 3rd Volunteer Battalion the Gloucestershire Regiment: Frederick St. John Bullen to be Surgeon-Lieutenant. Dated May 13th, 1903. 1st Volunteer Battalion Princess Charlotte of Wales's (Royal Berkshire Regiment): William Maskelyne Parham to be Surgeon-Lieutenant. Dated April 28th, 1903. 4th Volunteer Battalion the Durham Light Infantry: Surgeon-Lieutenant S. W. Plummer to be Surgeon-Captain. Dated April 18th, 1903.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Glasgow Companies: James Walker to be Lieutenant. Dated May 13th, 1903. The Manchester Companies: Lieutenant J. Collier to be Captain. Dated May 9th, 1903.

VOLUNTEER INFANTRY BRIGADES

Argyll and Sutherland: Surgeon-Lieutenant-Colonel D. W. Currie, 7th (Clackmannan and Kinross) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders), to be Brigade-Surgeon-Lieutenant-Colonel whilst holding the appointment of Senior Medical Officer of the Brigade. Dated May 13th, 1903. Gordon: Surgeon-Lieutenant-Colonel A. Mitchell, 3rd (The Buchan) Volunteer Battalion the Gordon Highlanders, to be Brigade-Surgeon-Lieutenant-Colonel whilst holding the appointment of Senior Medical Officer of the Brigade. Dated May 13th, 1903. Liverpool: Surgeon-Lieutenant-Colonel G. Westby, 2nd Volunteer Battalion the King's (Liverpool Regiment), to be Brigade-Surgeon-Lieutenant-Colonel whilst holding the appointment of Senior Medical Officer to the Brigade. Dated April 4th, 1903.

EDINBURGH COMPANY ROYAL ARMY MEDICAL CORPS VOLUNTEERS.

Former members of this company will be interested to know that the instructor, Staff Sergeant Lloyd, R.A.M.C., who has been attached to the Edinburgh company of medical students for the past 14 years, is about to retire into civil life. It is proposed to mark the occasion by presenting to the instructor some suitable expression of the friendly relations which have existed for so many years between him and the members who have passed through his hands. Towards this end any subscriptions sent by former members will be received and acknowledged by Major Hepburn, M.D., R.A.M.C.V., Anatomy Department, University of Edinburgh.

THE ROYAL MILITARY TOURNAMENT.

The tournament which opens at the Agricultural Hall to-day (Friday) promises to be in no way behind its predecessors. The *pièce de résistance* this year will represent the Delhi Durbar and this fact alone should be the means of securing a "full house" every day As our readers know, the military charities benefit largely by this annual tournament

ASEPTIC AND ANTISEPTIC SURGERY

To the Editors of THE LANCET

SIRS,—The discussion on the above subject in THE LANCET of February and March,[1] now coming to hand here, appeals to the surgeon no matter in what part of the globe he may be practising his art It may be taken for granted that any radical advance in surgery must be of world wide application Such is true of antiseptic surgery but the champions of aseptic technique have still their case to prove It would be interesting to know how they would apply their system in the following circumstances Since last autumn the survey has been in a series of temporary camps in the Ashanti jungle between Obuassi and Kumasi The bush is cleared and the camp built and we enter into occupation within the week Each of these camps is occupied for a period. varying from four to five weeks only, so of course everything is in the rough Ever since we left Obuassi the labourers, of whom there are several hundreds, to a greater or less extent have been suffering from sloughing phagedæna which Manson[2] writes is with difficulty to be distinguished from hospital gangrene The carriers of infection in these cases are flies, as I expect to be able to bring evidence to prove at some future date Our water supply is so bad (although it is the best available) that the drinking water is always coloured even after careful boiling and filtration, stinks in the upper compartment of the Berkefeld filters, and upon one occasion after filtration turned rose pink permanganate solution instantly brown

On Monday, March 23rd, at 9 P M, in the midst of a tornado with rain pouring down as it only can in the tropics, four men arrived at our camp carrying a hammock composed of a bamboo and some sacking in which lay huddled up a man with his right foot cut almost completely through horizontally, opening up the ankle joint from the inner side outwards. The man was soaked through, lying in a pool of blood and dirty water, and was very much collapsed The injury was caused I was informed by an axe which had slipped while the man was working with one of the clearing gangs further down the line He had been brought for six miles or more through the rain storm and dark over a roughly cleared track On examination by the light of a hurricane lamp I found a tremendous gash full of leaves and dirt with which an endeavour had been made to arrest hæmorrhage The ankle joint was sheared clear through the stroke having severed the posterior tibial artery which was feebly bleeding The wound was well washed out with 1 in 2000 perchloride lotion[3] and dressed with sal alembroth gauze and chinosol absorbent wool (the only antiseptic dressings available) A wisp of moistened gauze was also wrapped round the leg below the knee to disinfect the skin should it be found necessary to proceed to amputation The man was then carried over from the messroom and put for the night into a little hut which had been built at the end of the white camp to contain a lunatic suffering from guinea worm abscess The patient had to be moved outside with his guard to make room

Next morning as soon as things could be got ready after daylight and permission to do what was necessary obtained from the patient, chloroform was given and the injured limb was thoroughly examined The lower part of the foot was dead and cold, the ankle joint was injured and exposed and the tarsus was divided horizontally Not sufficient skin could be obtained to make an external lateral flap at the ankle, so amputation was performed at the seat of election, as it was hoped that at least a peg leg might be available in the country somewhere As no gut was obtainable for ligatures the main arteries were tied with silk soaked in perchloride lotion (1 in 1000) and the smaller bleeding points were commanded with pressure forceps, which were afterwards twisted off. The ends of the silk ligatures were led outside, and a gauze drain was inserted into each angle of the flaps The whole stump was dressed with sal alembroth gauze and chinosol wool The operation was carried out in the paymaster's hut, the patient lying on a litter made of split green palm rib, supported on a folding table and a packing case. The paymaster took over the chloroform after the patient was under and the junior assistant engineer, who was convalescing from an attack of fever manipulated the leg as directed When the patient came to from the chloroform he was tied firmly to the litter with creepers so that he could not move, while the stump was rested gently on a pillow made of straw bottle cases and newspapers In the evening his pulse was good though quick and his temperature only 99° F A watchman was left to guard him during the night and to give him drink or to attend to him generally Next morning I was informed that the patient had undone his bonds and wriggled himself loose and had got his dressing off I found the stump partly lying within the dressing but freely exposed to the air and the flies buzzing round The surface was at once washed with perchloride lotion (1 in 1000) and a 1 in 2000 lotion was syringed into the angles of the flap That evening the temperature was 100 2° F and next evening 101 4°, but the discharge was serous and not offensive in the least This was the highest temperature reached On Friday, March 27th, the dressings ran out but the principal medical officer at the fort at Kumasi kindly gave me two rolls of absorbent wool and some old field dressings These latter were split up and the contained gauze from them and the absorbent wool were soaked in perchloride lotion (1 in 2000) and dried in the sun With these the stump has been since dressed and for the last two days the evening temperature has not been above 99° F The stump looks healthy, there is very little discharge, and the man is free from pain and eats and sleeps well

The future progress of the case is of course doubtful in a country where apparently healthy skin breaks down into gangrenous ulcers and where Manson advises that no operative interference unless imperatively necessary, should be undertaken on account of the danger of tetanus To sum up then, by the use of antiseptics (1) a wound filled with dirt of all kinds does not cause general infection, (2) an operation conducted with scratch materials and scratch assistants gives a healthy stump, (3) a stump is exposed to the attacks of flies in an insanitary hut but does not become infected to any extent, and (4) dressings and water of doubtful character have been used without evil effect Can our aseptic champions suggest any feasible procedure by which such results could be obtained by their methods? My antiseptic outfit, with the exception of four dressings of gauze and wool, consisted of a four ounce stoppered bottle of perchloride soloids easily carried in the breast pocket

I am Sirs, yours faithfully,

CHARLES S PATTERSON, M B Edin, M R C S Eng,
Medical Officer Obuassi Kumasi Survey Gold Coast
Government Railways

Eighty two Mile Camp March 31st, 1903

THE SPITTING NUISANCE—SPITTING IN PUBLIC-HOUSES

To the Editors of THE LANCET

SIRS,—As a means for the prevention of tuberculosis it is chiefly important that spitting should be stopped in places where it is most likely to do harm Of all places of resort probably the public house is the most fruitful source of phthisis It has been found that in France the amount of phthisis varies with the amount of alcohol drunk and the English Registrar General has shown that public house servants suffer from this disease to a far greater extent than any other class of the community It is these servants who sweep out the bars In poor districts it may be safely said that every public house bar is visited by at least one consumptive every day and he probably spits on the floor while there

I have formed the opinion, on evidence as conclusive as it seems possible to get that the majority of adult male consumptives in my own district have derived the infection from the public house *It is obvious then, that of all* places where it is desirable to stop spitting the public-house is by far the most important. Yet I am informed that the terms "public hall, public waiting-room, or place of public entertainment," as used in the Glamorganshire by-law against spitting, do not include "public houses." If so, it is most important that these should be specifically included in any by-laws made for the County of London. Besides being pre-eminently desirable it is, I believe, perfectly practicable to stop spitting in public-houses. They are under continual police supervision and it is to the interest of the landlord and his servants to keep their bar clean. The publicans are becoming aware of the danger they run from the infection of phthisis and many of them would be glad to join in an effort to reduce this danger.

---

[1] THE LANCET Feb 14th (p 475) and 28th (p. 611) and March 7th (p 68[illegible]) and 21st (p 837) 1903

[2] P Manson: *Tropical Diseases* p 607

[3] Made with soloid [illegible] perchloride (B and W) and the boiled filtered water of doubtful character

In the borough of Woolwich, with very few exceptions, the licensed victuallers have posted up in their bars notices requesting customers not to spit on the floor, but they say that at present they are powerless to enforce such notices. A by-law would effectually strengthen their hands. I venture to say that any by-law against spitting which does not apply to public-houses will produce but an insensible effect in the diminution of tuberculosis.

I am, Sirs, yours faithfully,
SIDNEY DAVIES,
Woolwich, May 12th, 1903. Medical Officer of Health.

CERTIFYING FACTORY SURGEONS.

To the Editors of THE LANCET.

SIRS,—It has been pointed out to me that my letter of May 9th might infer an intention on the part of our association to take advantage of the Home Secretary's presence at the annual dinner to elicit an expression of opinion on the question of fees paid to certifying surgeons. As I must acknowledge the possibility of such an interpretation I take the first opportunity open to me of disclaiming any such intention, anything of the kind indicated being so obviously out of place at a purely social function. The view I expressed in the last sentence was purely a personal one of general application and not to be regarded as authoritative.

I am, Sirs, yours faithfully,
W. F. DEARDEN,
Honorary Secretary, Association of Certifying Factory Surgeons.
Manchester, May 11th, 1903.

"GOUTTES DE LAIT."

To the Editors of THE LANCET.

SIRS,—Perhaps you would be so good as to devote a few lines of your valuable space to informing your readers that at a meeting of the staff of the Royal Hospital for Children and Women held on May 4th the following motions were unanimously carried :—

1. That this committee approve of the principle of an infants' milk depôt.
2. That if the borough council establish a depôt in the immediate neighbourhood of this hospital the staff will do what they can to induce patients to use it.

These resolutions were approved by the committee of management at a meeting on May 5th and the secretary was instructed to prepare a petition to this effect to be laid before the borough council of Lambeth.

I am, Sirs, yours faithfully,
J. HOUSTON, Secretary.
Royal Hospital for Children and Women, Waterloo Bridge-road, S.E., May 7th, 1903.

THE AERIAL CONVECTION OF SMALL-POX.

To the Editors of THE LANCET.

SIRS,—I should feel much obliged to any of your readers who would furnish me with the reports upon, or well-authenticated examples of, the spread of small-pox around small-pox hospitals by aerial convection. The well-known cases of the Fulham Hospital, the Sheffield, Bradford, Warrington, and Glasgow reports, as well as Dr. J. C. Thresh's recent interesting example, I am, of course, already acquainted with. In connexion with this request I may express a hope that the Local Government Board may eventually see its way to publish annually a *résumé* of the many valuable annual reports furnished by the medical officers of health throughout the country. The Board receives a copy of each, but many of these reports are not printed and even then they are not obtainable ; moreover, it would be practically impossible to read them all. THE LANCET gives interesting reviews on the most important cities ; this does not, however, meet the need I with others feel of an annual volume giving a *résumé* of the experiences in sanitary problems. Some years ago I wrote to THE LANCET advocating such a publication by the Local Government Board and subsequently Dr. Paget informed me that he had already done so. Perhaps I may also mention that the late Sir Richard Thorne, chief medical adviser to the Local Government Board, wrote to me that the proposal had his most cordial good wishes but that he feared the expense of such a publication would stand in the way. The financial loss to the Government would, however, be well repaid by the educational gain to the medical officers of health. The solution of many important public health questions is at present retarded by the difficulty of obtaining the experiences of other workers.—I am, Sirs, yours faithfully,

ANTONY ROCHE, M.R.C.P. Irel.,
Professor of Public Health, Catholic University Medical School.
Dublin, May 10th, 1903.

"RETURN" CASES OF TYPHOID FEVER (?).

To the Editors of THE LANCET.

SIRS,—I write rather to elicit than to contribute information on a subject of considerable practical importance. While it has long been known that the exit of a scarlet fever patient from hospital is occasionally followed by the admission of other cases from the home to which that patient has returned, I am not aware that definite statements can be made as to the period at which cases of typhoid fever cease to be foci of contagion and sources of real danger to the community. A patient, A, for instance, is admitted to hospital with anæmia and after nearly three weeks' residence the temperature rises and typhoid fever develops. In the ward are two patients, B and C, convalescent from typhoid fever. On the day of A's admission B is in her third week of normal temperature and C in her fourth week. A is said to have been in close proximity to B. Had B or C gone to A's home and A been admitted three weeks later with symptoms of typhoid fever, A must, I think, fairly have been considered as a "return" case. And yet medical officers of health assure me that such cases are practically unknown and that their experience shows that during convalescence typhoid fever is not transmissible. On the other hand, I notice that Professor Osler (fourth edition of his "Principles," p. 31) states that "bacilli may be present in the urine for years after the attack" and mentions that "during 12 years 20 physicians, nurses, or patients contracted the disease in his wards" (p. 5). Presumably, from the large number of cases under Professor Osler's care, none of these patients contracted the disease from a convalescent.

I am, Sirs, yours faithfully,
A. A. WARDEN,
Physician to the Hertford British Hospital, Paris.
Paris, May 6th, 1903.

THE STUDY OF VENTILATION.

To the Editors of THE LANCET.

SIRS,—Many years' practical experience as a sanitary engineer induces me to ask you kindly to insert this letter suggested by Brigade Surgeon-Lieutenant Colonel D. Boswell Reid's communication in THE LANCET of May 2nd, p. 1264. I fully agree with him that fire is the best purifier of contaminated air and assert that the simpler the method of governing the movements of air the better is it for all concerned. It is unfortunate, I think, that in this country a great many people appear to hold exactly the opposite view, forgetting to bear in mind the great difficulty—I had almost written impossibility—of controlling the movement of air, which is, say, 12 feet above the floor level. Ventilation and warming should go hand in hand and one and the same person, I maintain, should provide for both requirements, and I am more convinced than ever that it will be found that properly constructed fireplaces with simple open fires will give the best result from both the point of view of comfort and that of health.

I was informed quite recently that in order to provide a permanent system of reliable and beneficial ventilation the London School Board have out of nearly 300 schools scarcely two schools with the same system, while in the infant schools the best results are obtained with open fires. A very interesting annotation in THE LANCET of Feb. 28th,

p. 604, drew your readers' attention to evils arising from cooking meat in the oven of a close fire range and the loss people suffer by not using an open fire for cooking meat, &c., in front of it. It is impossible to roast properly in front of a close fire range and there is scarcely a house in which close fire ranges are used but that the atmosphere at the time of cooking a joint gives immediate knowledge of the fact directly one enters the house. I do not despair, however, of seeing at no distant time an open fire range that shall be economical in use in every way and free from the reproach of committing a sin against the cleanliness and purity of the air. I trust that further contributions will be made to THE LANCET upon this very important subject.

I am, Sirs, yours faithfully,

May 5th 1903. D. T. BOSTEL, Senr.

FREE ANTITOXIN TO THE MEDICAL PROFESSION.

To the Editors of THE LANCET.

SIRS,—With reference to remarks which have recently been made in THE LANCET *re* the above I should be glad if you will allow me to say that, so far as I know, the urban sanitary district of Swinton and Pendlebury was the first in this country to adopt the practice of gratuitously supplying antitoxin to its local medical practitioners, such course having been taken upon my recommendation early in the year 1901.

I am, Sirs, yours faithfully,
SAMUEL HOSEGOOD,
Swinton, Manchester, April 29th, 1903. Medical Officer of Health.

⁂ In our issue of May 2nd we published a letter from Mr. E. C. Bousfield stating that nearly six years ago the then vestry of Camberwell commenced the free distribution of antitoxin.—ED. L.

JACOBI'S ATLAS OF SKIN DISEASES—SMALL-POX AFTER VACCINATION: A CORRECTION.

To the Editors of THE LANCET.

SIRS,—May I request you to insert in your esteemed journal the following remarks which I feel obliged to make in reply to Dr. C. Killick Millard's letter published in THE LANCET of April 25th, p. 1197, under this heading? I regret my delayed reply which has been due to Dr J. J. Pringle's illness.

Dr. Millard's criticism refers solely to Plates XXXV*a*–XXXV*c* and the corresponding text which have been added by Dr. J. J. Pringle without my knowledge and authorisation. For this reason I refrain from any comment on Dr. Millard's unkind references to the "German author" and refer him to the "English translator."

I am, Sirs, yours faithfully,
Professor E. JACOBI,
Director der Dermatolog. Universitats-Klinik.
Freiburg-i.-Breisg., May 12th, 1903.

To the Editors of THE LANCET.

SIRS,—I am greatly indebted to you for the kind review of the Portfolio of Dermochromes by Professor Jacobi, for the English adaptation of the text of which I am responsible. The statement which you indicate in the addendum which I made to Professor Jacobi's text, that variola does not occur in people who have been vaccinated, is, *I admit, too* absolute and will be amended in the second edition.

I am, Sirs, yours faithfully,
Lower Seymour-street, Portman-square, W., J. J. PRINGLE.
May 13th, 1903.

CONICAL CORNEA.

To the Editors of THE LANCET.

SIRS,—The recently circulated *brochure* by Sir Anderson [illegible]

evidently not equalled by his knowledge of the literature of the subject and with a little trouble he might have ascertained what others had done in the same field with the cautery long before the date (1895) of his communications to the medical press. If he will only turn to the *British Medical Journal* of Feb. 23rd, 1889, he will find a short paper read before the section of ophthalmology at the Glasgow meeting of the British Medical Association in the previous year, in which I refer to the works of the late Dr. E. Andrew and Mr. W. J. Cant on the use of the cautery and in which it is stated that "the plan adopted by these operators differs in at least one important point from the method employed in the cases which I am about to relate. The essential difference consists in the fact that the two surgeons named make a point of opening the anterior chamber so as to allow a continuous drainage of the aqueous for a prolonged period and so purposely use a needle capable of penetrating the corneal tissue; whereas I hold that complete penetration of the cornea with the discharge of the aqueous is a *result to be avoided* as unnecessary and dangerous, and believe that the same object as regards the reduction of conicity can be attained without the escape of the fluid." Yet, Sir Anderson Critchett says in his pamphlet that "till about three years ago the universally accepted plan of applying the cautery in cases of conical cornea was to use it almost at red heat and to *persevere until a spurt of aqueous showed that the anterior chamber had been penetrated.*" My first case was operated on in 1886—14 years before the time mentioned by Sir Anderson Critchett. I do not think therefore that he can claim either priority in, or "initiation" of, this method of treating conical cornea, and I am sure that he would be the last willingly to deprive benighted [illegible]

Liverpool, May 11th, 1903. RICHD. WILLIAMS.

SUBSTITUTION IN THE SPIRIT TRADE.

To the Editors of THE LANCET.

SIRS,—From the answers given by the Chancellor of the Exchequer in reply to questions by Mr. T. M. Healy on Thursday last it is apparent that the dangers attendant on the use of promiscuous materials in the manufacture of potable spirits, more especially of so-called "Scotch whisky," have not yet been recognised in official circles. The significance of Mr. Ritchie's statement that "no doubt beet molasses is used to some extent" may not be quite clear to many medical men at first sight and I therefore venture to trespass on your valuable space in order to explain the full bearing of his admission. Beet molasses constitute the residue or dregs of beet sugar manufacture; they differ from sugar-cane molasses in that they contain a very large percentage of substances of a basic and quasi-alkaloidal nature. The substances in question are fatty amines, bases closely allied to the ptomaines, and bases of the pyridine series. The percentage of these bases in beet molasses is so high that some of them or their derivatives are actually obtained on a manufacturing scale from this source. The poisonous nature of some of these bases is well known; it is further a matter of common knowledge that it is next to impossible to remove them completely from spirit by any known process. And yet the Chancellor of the Exchequer calmly admits that "no doubt beet molasses is used to some extent." Comment is needless.

In reply to another question put by Mr. Healy Mr. Ritchie gave a reply calculated to convey the impression that chemical analysis was not able to distinguish between various classes of spirit. This reply is, in my opinion—and I may say that I have a fairly extensive experience in this connexion—based on erroneous information and is to a great extent misleading. That chemical analysis cannot distinguish in *all* cases I readily admit, but is there any branch of food analysis of which the same may not be said? That it (chemical analysis) can distinguish in many cases between different spirits, particularly between patent still spirit and "all-malt" whisky, is nevertheless a fact which my own personal experience fully confirms. Quite recently I have examined several specimens which are described and blended in such a manner as to lead the purchaser to believe that they are genuine "all-malt" Scotch whiskys, and these, by the analytical figures alone, were plainly proved to be nothing of the kind. In several cases, also, I have been able, judging by taste and the analytical figures combined, not only to show that the articles were falsely described, but also to determine the material from which these spirits were manufactured. With a little research on the chemistry of whisky, together with a number of standards obtained by an examination of the greater number of the spirits actually produced and blended, it would, in my opinion, be by no means difficult to stop the nefarious traffic which is now proceeding. I inclose my card.

I am, Sirs, yours faithfully,

May 11th, 1903. "EXPERT."

A QUERY IN EMBRYOLOGY.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if any of your readers could throw some light on the following occurrence. A blue Persian pedigree she-cat was sent to an equally pure-bred tom of the same species on Feb. 20th. She remained there from the 20th (a Friday) till the following Monday, the 23rd, and, according to the owner of the sire, was served at least twice. Her kittens would have been due on or about April 27th. On the day after her return home she was seen in the garden in company with a black-and-white tabby tom. Pregnancy duly went on but the kittens were born on May 2nd. They were six in number and were all coarse-made, big-boned, and black-and-white. Was she impregnated by the blue tom? If so, was a second impregnation effected by the black-and-white tom and could the spermatozoa of the latter have destroyed those of the blue tom? Or was it simply a case of "maternal impression"? Or was there no impregnation by the blue tom and an ordinary impregnation by the black-and-white? Why was delivery delayed nearly a week? I may add that the cat has been put to the same blue sire on two previous occasions and has had two perfectly coloured blue litters as the result.

I am, Sirs, yours faithfully,

May 11th, 1903. OXON.

A POINT IN THE SELECTION OF THE HONORARY MEDICAL STAFFS OF PROVINCIAL HOSPITALS.

To the Editors of THE LANCET.

SIRS,—The question as to the desirability or otherwise of honorary members of the medical and surgical staffs of provincial hospitals (other than cottage hospitals) being in partnership together is one which arouses interest in certain towns and one on which an opinion from THE LANCET would be of service. In the case of the large hospitals in London and the larger cities no such thing is now possible, I believe, whilst in the more important provincial hospitals there is a rule prohibiting such partnerships. The question arises particularly in such cases as the following. A small town develops in the course of time into a large one, the centre of a district. In the first place, a small hospital or dispensary has arisen, worked by two or three medical men. With the growth of population and importance this has evolved into a comparatively large infirmary; and the staff, whilst still maintaining the status of general practitioners, are exceptionally favoured in public estimation. There then develops, naturally, a tendency on the part of the staff to work the institution for their own private benefit and to keep out outsiders. Having almost complete influence with the committee of governors, many of whom know nothing of medical matters, this can often be done. Rules are framed which put difficulties in the way of outsiders, whilst a partner or relation of one of the staff may be afforded exceptional facilities. Undoubted abuses occur. I know of one case where a firm of three members practically managed a county infirmary for many years and were enabled in this way largely to monopolise the general practice of the district.

It must be remembered that it is not by any means necessarily the best men in point of qualification who secure these appointments, though possibly after years of experience obtained from the appointments they may eventually become so. Also, the staff are in open rivalry as *general practitioners* with their less favourably placed brethren around. Thus arises much jealousy, so that outside practitioners often prefer to send their patients to an infirmary at a distance rather than to the one at home, so impairing the usefulness of the institution. It appears to me that by adopting a rule prohibiting the system of partnership on the staffs of infirmaries much good would result in checking these evils. Of course, my remarks do not apply to cottage hospitals or to districts where a few medical men only are available, but to the larger centres of population with plenty of medical material ready and anxious to serve.

I am, Sirs, yours faithfully,

May 8th, 1903. M.D.

*** Undoubtedly the staff of a hospital ought to be selected on its merits. The rule that no two members of a firm should be upon the staff together might in many cases prevent nepotism even if, in a few cases, it might exclude the fittest candidate.—ED. L.

THE
FOURTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

(FROM OUR SPECIAL CORRESPONDENT.)

THE HOTEL AND LODGING HOUSE SCANDAL.

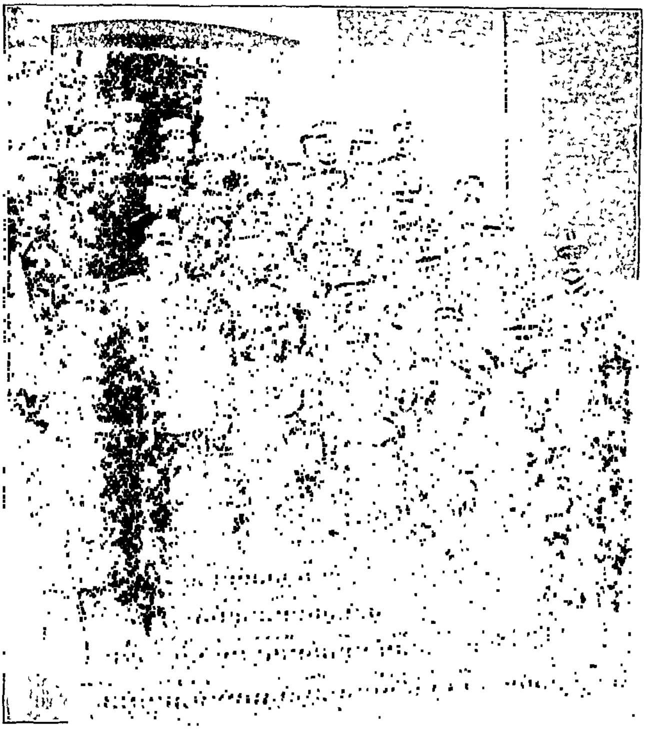
Madrid, May 4th.

IF only for the sake of future congresses and as a warning it is necessary to allude again to the question of hotel and lodging accommodation. This is the more indispensable as on the present occasion many regrettable incidents have occurred. The offices of the Congress have been disturbed by the sounds of violent quarrelling and protestation. Abusive words have been used and quite a scandal has been created. In such circumstances some explanation is necessary, particularly as rumour and gossip are apt to place matters in their worst light. As explained before, M. Ulrich Frei had been engaged by the organisers as a paid manager or clerk to look after the interests of the foreign members of the Congress. He had acted in a similar capacity during the congresses held in Paris in 1900. The work soon became terribly absorbing and had to be attended to night and day. The Congress was to meet at a most inappropriate date. First of all the Easter holidays, when it is the custom to crowd into the large towns, were scarcely terminated. Then many travellers were returning to Madrid from the Seville and other Easter fairs. The Congress met on April 23rd and on the 26th there were general elections throughout Spain and a general election always draws to the capital a large number of political wire-pullers and others. The executive committee of the International Congress of Medicine also clearly saw that more members would attend than had been expected. It was given to understand that the capacity of the hotels in Madrid would not suffice to accommodate so many persons coming to the capital for different reasons but at the same time. At this stage what seems to me to be a great blunder was committed. The executive committee should have washed its hands completely of the question of hotel and lodging accommodation or else should have kept the matter absolutely and in every detail under its own control. The safest course to pursue and that which is very generally adopted for similar congresses is to institute, many months in advance, an inquiry as to the number of rooms and the prices to be charged which the different hotel and lodging-house keepers think that they will have vacant at the date indicated. These details being printed should be sent to every member of the congress as soon as he notifies his intention of attending and then every member, without the intervention of any agency whatsoever, knows where to go or to write for rooms. The congress committee simply gives all the information it is able to gather. At most the committee stipulates with the hotel keepers that they will keep a certain number of their rooms free at the price mentioned and not make other contracts with agencies or individuals. If the committee does not content itself with merely giving information it will need much business capacity and very strict supervision before it can safely venture itself to supply the rooms. As I said at the time, to the "corner" in hotels formed by the travelling agencies the medical men had opposed a collective organisation of their own. This certainly would have been a very public-spirited and admirable thing to do. I was misinformed and like most members of the Congress I was deceived by appearances.

When the work became overwhelming for the reasons described above M. Frei asked the directors of the Congress whether he could as an individual and apart from the

Congress treat with a travelling agency for the supply of rooms to the members of the Congress. Trusting to M. Frei's well-known and established honour and above all believing that it would be of help to the foreigners who were coming to Madrid, the committee gave its consent to this arrangement. The one prevailing desire was to help the foreigners and to prevent their being exploited by the hotel keepers The idea was that the agency and not the Congress would ask members to state what sort of rooms they required and to send 50 francs in advance. The agency was then to go to the hotels and to treat for the rooms telling the hotel keeper to add to his usual charge 10 per cent. so as to cover the working expenses. This charge was made openly, there was no attempt to conceal the fact, but it was always held to have been done outside the Congress and not as part of the Congress management. This was the theory; what actually happened and other places to make inquiries an prices doubtless these poor touts stipulat for themselves as apart from what the The door was thus thrown open to all man

But now another blunder was commit the whole affair to grief. In all such ma tion success mainly depends on extreme method of procedure and in the reduction to a minimum. Instead of this and before Logements would consent to indicate to th where he might find a room he was called upo days' board and lodging in advance. In exc hard cash he got a number of green coupons. protested that he was not going to remain in M days; it was pointed out that there was on the c printed promise to the effect that the money wou returned for the coupons that were not used. As but fo



The military delegates at the International Congress of Medicine at Madrid. The photograph is taken at the entrance of the Military Hospital.

differed considerably. First of all no one imagined that what was denominated as the Service des Logements du XIVe. Congrès International de Médecine had nothing to do with the Congress. Then as the offices of this lodging service were on the same premises as the Congress itself this fact still further confirmed the impression that it was an organisation formed to protect the members of the Congress from the agencies and not itself an agency in disguise. Of course, this agency was not at all desirous to undeceive the members of the Congress. It was preferable to be considered as officially representing, and authorised by, the Congress. As the accommodation in the hotels did not suffice the agency advertised asking private people to offer the use of one or more rooms in their own homes. This brought a flood of answers, far more than was required. Then some men, miserably paid, were sent round to various small hotels the members of the Congress were likely to stay ten days this meant that the majority would have to waste some of their time and the time of the clerks or cashier in getting such portions of their *money* back. *Then there* was the difficulty of changing foreign money into Spanish. However, these were but inconveniences. The first serious difficulty was that the prices charged were not at all cheap, as the members of the Congress had been led to expect. Then when on being shown their rooms and experiencing the accommodation received members of the Congress complained of the exaggerated charges the landlord might, perhaps, explain that he did not receive as much as the charge made for the coupons. *A member* of the Congress who had come from New Zealand was very bitter. He told me that it was materially impossible for anyone to come a greater distance to attend the Congress. No notice had been taken of this fact or that on was delegated by a university. He had not been invited st where and was left to the tender mercies of the Service of s Logements which had provided him with a room for 9 pesetas per day. It was not particularly clean, the service was very insufficient, but he was not going to complain because his landlady was very obliging, did her very best, and was receiving only 15 out of the 20 pesetas that he was paying.

This state of affairs did not last long; the proprietor of a hotel, finding that his visitors were grumbling at the heavy charges, betrayed the whole situation. He said that he was quite willing to accept much less if the payments were made in cash instead of in coupons. Anxious to please his visitors he advised them, to go to the Congress office, to get reimbursed for their coupons, and then to deal directly and at a cheaper rate with him. No sooner had one hotel keeper done this than others thought themselves obliged in self-defence to follow his example. Then lodging-house keepers and others began to do the same thing. Thus suddenly and unexpectedly a tremendous rush took place and a very large number of members of the Congress wanted to be reimbursed for their coupons. Of course, this was unexpected. Measures had been taken to reimburse the value of a limited number of coupons but a wholesale rush of this description had not been anticipated. At first the claims were readily met but after a while the money in hand ran out and a panic ensued. A story got about that coupons had been forged and that money had been given to the bearers of false coupons. It was even stated that 7000 pesetas had been obtained in this manner. Now the lodging-house keepers got alarmed and some refused to accept the coupons and in one or two cases threatened to turn their visitors out. Thus there were some members of the Congress who cou d'neither get reimbursed for their coupons nor lodged for them. They were therefore obliged to pay twice—once for the coupons and once again in cash to their landlords. It may well be imagined that such a situation became intolerable. An appeal was now made to the Governor of Madrid who sent a commissioner of police to make inquiries. But the commissioner of police did not find anything wrong. No forgeries whatsoever had been committed, no false coupons had been presented, and no claims had been discarded or payments refused. At one moment the management was short to the extent of 7000 pesetas; the payments ceased for a while till this amount could be procured, but there were no repudiation of any liability entered into and no reason for arresting anyone. Inquiring of the secretary-general of the Congress I was informed that every penny would be reimbursed. The honour of the country is engaged and not a penny will be withheld. But all the same big blunders have been committed and these are all the more regrettable as nothing could have been more cordial, more obliging, or more courteous than the general disposition of all the Spaniards connected with the Congress. No people could possibly have been more anxious to please. Business ability and foresight were evidently wanting; kindness of heart and good feeling were there in abundance.

THE SECTIONS.

MEDICINE.

At the meeting of this section on April 28th a paper was read by Dr. **JULIUS GUEZDA** of the clinique of Professor Leyden in Berlin, on "Salocreol." Salocreol, he said, was a preparation which was derived from beech tree tar and which contained all the various phenols of this tar combined with salicylic acid. It formed an oily fluid insoluble in water but readily soluble in alcohol or ether. By the action of alcohols as well as by the organism salocreol was saponified into its components, one of which (salicylic acid) appeared in the urine as salicyluric acid, the presence of which could easily be proved with ferric chloride, when a violet colouration occurred. The primary idea in producing salocreol was to obtain a compound which could be applied *locally* in acute rheumatism. It was thought that the untoward effects of salicylic acid on the heart and kidney would be diminished if the salicylic acid were at the moment of penetration through the skin to combine at once with the glycocoll of the proteids of the rheumatic exudation. As the beneficial effect of phenol injections into hydroptic joints was a well-known fact, so there could be well expected an increased action by a combination such as salocreol. The trials with salocreol which were performed in the clinique of Professor Leyden at Berlin gave very good results and while in regard to acute rheumatism affecting the joints sufficient experience had not been obtained, there was observed a very prompt action of salocreol in cases of erysipelas. The patients experienced in the parts affected by erysipelas an immediate relief as regards the tension of the skin and there were cases in which the utterly closed eyes could be partially opened in 12 hours. If the tissues in the immediate neighbourhood of the part affected with erysipelas were treated with salocreol the spreading of the erysipelas could be stopped. Large doses were advantageously administered on the first day of treatment at intervals of two hours during the day-time. Salocreol had a marked effect in reducing swollen glands and cases of lymphadenitis after measles, scarlet fever, and diphtheria were improved in a remarkably short time. Similarly good results were obtained in cases of scrofulosis.

Dr. **ARNOLD LORAND** (Carlsbad) read a paper on the Relations between Diabetes, Acromegaly, and Graves's Disease. These three diseases had many common features. They could be caused by the same agents—infectious diseases, mental emotions, &c. Traumas (nervous shock) could not only cause diabetes but also Graves's disease, and even cases of acromegaly had been reported after accidents. Glycosuria, polyuria, polydipsia, and polyphagia might appear in any of them. In these three diseases there could be found changes in the vascular glands: in Graves's disease in the thyroid gland, in acromegaly in the hypophysis (anterior lobe), and according to the last researches of Opie, Weichselbaum, Hoppe-Seyler, and others in nearly all cases of diabetes there could be found alterations in the vascular islands of Langerhans in the pancreas. These islands constituted a vascular gland of the type of the thyroid or the hypophysis. The pathological alterations in one gland produced also alterations in the other glands. Thus changes in the pancreas produced changes in the thyroid gland, and alterations in the thyroid gland might, *vice versâ*, produce changes in the pancreas. In Graves's disease (hyperthyroidea) glycosuria was very frequent and even true diabetes was not uncommon. According to the researches of Dr. Lorand glycosuria existed in acromegaly when there were symptoms indicating a hyperactivity of the thyroid gland. Glycosuria or diabetes was only present in such conditions where there existed also a hyperactivity of the thyroid gland. This was the case after infectious diseases in which, according to the researches of Roger and Garnier, there existed very frequently a hypersecretion of colloid substance, this being confirmed by Torri. It was equally so after mental emotions, after certain poisons and drugs, which according to Roger and Garnier could also cause a hypersecretion and even later an exhaustion of the gland. The glycosuria of chlorotic persons and the glycosuria which occurred in syphilitic subjects, as a rule observed only in women, depended upon the swelling of the thyroid which had been observed only in women by Engel Reimers. Lactosuria and diabetes, which might appear sometimes during pregnancy, depended upon the hyperactivity of the thyroid in this state. At the end of lactation and pregnancy they might disappear with the exhaustion of the gland. The glycosuria which sometimes appeared in cholelithiasis depended upon the hypersecretion of the thyroid observed by Hürthle in stagnation of the bile. It was a fact that extracts of thyroid gland might produce glycosuria and even diabetes. On the other hand, glycosuria was absent in all states of inactivity of the thyroid gland. It was never present in myxœdema (athyroidea). It was missing in hereditary syphilis, for in these cases there was an inactivity of the thyroid gland (retardation of growth). It was nearly always absent in cancer and tuberculosis, for in these diseases, as Dr. Lorand had established in another communication to the Congress, there existed an inactivity (atrophy) of the thyroid. The disappearance of glycosuria by the treatment with opium and shortly before death depended upon this fact. Diabetes was uncommon in children but so also was hyperthyroidea (Graves's disease). The prognosis of diabetes was better in advanced age (inactivity of the thyroid). The few rare cases of cured diabetes had occurred mostly after infectious diseases—syphilis, influenza (Holsti), scarlet fever (Zinn). As Roger and Garnier had proved there could be brought about in infectious diseases a complete exhaustion of the thyroid after a preceding hypersecretion. Dr. Lorand came to the conclusion that these three diseases were in very close relation to one another; pathological alterations were found in several vascular glands, in diabetes pancreas and thyroid gland were affected; hyperactivity of the thyroid gland could bring about diabetes especially when there were simultaneous changes in the pancreas.

Dr. HUERTAS BARRERO and Dr. GUSTAVO PITTALOGA brought forward a report upon the Causation and Prevention of Paludism. They agreed as to the relationship between mosquitoes of the genus anopheles and malaria The clinical manifestations of malaria were produced by three parasites which *must be looked upon* as three [illegible] ere distinct and not [illegible] three species were: [illegible] which caused quartan fever; (2) plasmodium (hæmamœba) vivax, causing tertian ague; and (3) laverania malariæ (hæmamœba præcox and hæmamœba immaculata) which gave rise to the severe æstivo-autumnal fever with its malignant forms. The relation of relapses and the epidemic season (June to December) had acquired an extraordinary importance of late years, for they seemed to point to the fact that parthenogenesis might play a part in their occurrence. There might, for instance, be a direct reproduction of sexual forms of micro-organisms in the blood of malarial patients, such reproduction occurring after longer and later periods and sometimes even after very long intervals from the apparent cure of the original fever, the macrospore, or female element, preserving the power of reproducing by division in the internal organs of its host, the results of the division giving rise to new generations of sporozoites. But the most important conclusion to be deduced from this theory of parthenogenetic relapse *is the possibility of the* rapid and multiple infection of innocent anopheles which happen to bite during June and July. These mosquitoes became infected with the sexual forms of the malarial parasite in the blood of old malarial patients and it was only from the parasite in this stage that a new generation of sporozoites could be developed in the mosquito's stomach. *The prevention of malaria was considered* under the headings of (1) destruction of the larvæ of the mosquito, chiefly by petroleum; (2) the improvement by drainage of malarial soils; (3) mechanical prophylaxis consisting in the protection of houses in a malarial tract by a fine metal meshwork, whilst the individual was protected during twilight and the night by mosquito nets, gloves, and veils; and (4) therapeutic prophylaxis consisted in the methodical care of all patients suffering from malaria whether of old or of recent standing—the prevention, in the strictest sense of the word, of malarial attacks by daily doses of quinine, such doses being given to everyone who was exposed to infection during the epidemic season.

SURGERY.

Dr. TRUMAN W. BROPHY (Chicago, Ill.) read a paper on the Surgical Treatment of Congenital Clefts of the Palate in Infants. He said that he was well aware that many eminent surgeons did not favour operations in early infancy for the cure of cleft palate and that few, comparatively, were familiar with the methods that he had devised and practised, but it was gratifying to realise that many who formerly questioned his method were now most enthusiastic advocates of it. The question of early operations had with him (Dr. Brophy) *passed the experimental stage*; an experience extending over a period of 20 years, with a careful examination of patients upon whom he had operated, was satisfactory evidence that the most desirable time in life to operate for congenital cleft of the hard palate was within five months of birth, preferably within three months, and this conclusion was based upon the results of clinical experience Some of his most satisfactory results were obtained in infants from ten days to three weeks of age. The operation was made by forcing the maxillary bones together, bringing the edges of the fissure in contact and securing union Among the reasons why he believed that early operations were most desirable were: 1. Surgical shock was less because the nervous system of a young child was not well developed and it was not therefore capable of receiving the same impressions that it would later in life; besides, young children usually reacted better. Hæmorrhage was very slight; moreover, all mental impressions were eliminated, it being well known that alarm and dread were amongst the most powerful factors in producing shock. *The operation* should be made upon the palate before that upon the lip It was a great mistake to commence at the oral opening and partially to close the only aperture through which a subsequent palate operation must be made. The surgeon needed all the space that could be secured, which was none too much in a small child. The lip operation was comparatively simple and trivial and it could be performed at any time, but the palate operation was made much more difficult if prior to that the lip had been closed. Should the intermaxillary bones protrude they must not be removed but should be carried back into their normal position. 2. Before the bones were fully calcified *they might be bent or moved without fracture. Bone* at birth was about one-half organic matter, hence the injury was really less in closing a cleft than it would be if the calcification were more complete. 3. If the muscles were very early brought into action they developed instead of atrophied and hence a good velum was secured with plenty of tissue, whereas if the operation was undertaken later in life, after the parts were shrunken through non-use, they could rarely be made to subserve the same service that organs which developed through natural employment could be made to do. It was well known that muscular tissue was more perfectly developed through action; in instances of cleft palate none of the muscles of the velum could be normally employed when the parts were not united and hence they remained in an immature condition through life. By operating at a very early age they were at once brought into use and their development was proportioned to that of other tissues. When the palatal processes of the maxillæ were united the development of the bones of the alveolar processes of the upper jaw assumed a form nearly or quite normal and when the teeth were erupted they would meet the lower ones or nearly so when the mouth was closed. The method described enabled them to restore in early infancy the normal relations of the superior maxilla and consequently the proper relation of the upper to the lower maxillary bone. In patients not having sufficient bony tissue to enable him (Dr. Brophy) to close the cleft by this operation without contracting the arch he *found rather to his surprise that as time went on the bones* developed and the arch spread until, when the upper teeth were erupted, they nearly, or quite, occupied the normal relation to the lower ones. 4 Following early operations there was much less deformity, for all the tissues, bony as well as soft, developed naturally and according to accepted types. When the operation was postponed for a few years it was very difficult to secure such results. 5. When the operation was made in early infancy the tissues united, the nasal accent did not develop, and speech was normal when the time came for learning to articulate. If the operation was not made until faulty habits of speech were acquired it was with difficulty that they could be overcome, even though the muscular parts were made sufficient. The method of procedure in operating for the closure of congenital cleft palate in a young child would, he added, be fully described and illustrated in the printed Transactions [illegible]

[illegible] the British Orthopædic [illegible] e *Treatment of Hallux* [illegible] hat for some time past there had been a movement in England in favour of allowing the human foot to develop its normal shape. Children were allowed to go barefooted or to wear sandals and adults who had arrived at years of discretion preferred comfort in walking *to the fashionable shapes of foot-covering. Comfort in* walking largely depended upon the perfectly normal condition of the foot, every part of which ought to perform its allotted function. The deformities to which he had to call attention were due almost always to interference with the special function of each toe by ill fitting boots. His paper did not discuss the question of ill-fitting boots but it was intended to describe the methods of correcting the deformities produced by them. The most important of these were hallux valgus and hallux flexus. These two deformities had mutual relations and most frequently the two were present in the same foot. In elderly adults it was not desirable to interfere by means of operative surgery to correct such deformities unless they were producing pain or other inconvenience It was only necessary for the patient to wear the most comfortable boots he could obtain and to treat any gouty condition which might be, and frequently was, present by suitable medical remedies. When operative interference was required for hallux valgus the best proceeding *was to take a wedge of bone from the metatarsal* bone of the hallux. An elliptical piece of skin was removed which must be made to include the bunion usually present in these cases and then a wedge was without difficulty removed from just above the articulation of the metatarsal with the phalanx. When the cut surfaces of the bone were applied to one another the inner margin of the foot should be in the same line with that of the toe; all bleeding being arrested the skin margins were brought together and the foot was fixed in an immobile apparatus. It usually healed completely before the apparatus need be removed. Hammer-toe or flexus digitus pedis was a painful affection and so unsuccessful had treatment been that some surgeons preferred amputation to any less severe method. Although Mr. Thomas had amputated in many cases further experience had convinced him that it was very rarely necessary. The second digit was most frequently affected where there was only one deformed hammer-toe. Next in frequency came the fourth but sometimes the whole of the toes were bent and so severely that the patient walked on the nails. In such cases no one would dream of amputating all the toes and treatment by other means was usually successful. If then they could treat multiple hammer-toe without operation they certainly ought not to require such a severe measure for one. Hammer-toe, when confined to the second digit, was nearly always associated with hallux valgus and many ingenious appliances had been devised for the correction of both. Mr. Thomas explained a simple appliance for the combined treatment of hallux valgus and hammer-toe which had proved of great value in his hands not only in these conditions but also in correcting deformities of the toes generally. He called it the "tomato splint." It was constructed of dentist vulcanite, aluminium, wood, brass, celluloid, or any other non-irritating material, in sizes which readily adapted themselves to the individual foot. Formed of one of the above materials it served as a splint, fitting to the under surface of the toes and affording a groove in which each toe lay in the normal position. The posterior border was concave and rested against the heads of the metatarsal bones. The upper surface had three grooves, one for each of the three middle toes, and two half grooves for the great and little toes. Between the grooves were raised septa, the one between the great toe and the next being higher than the others, and the septa were pierced so as to allow the strapping, tape, or elastic by which the splint was fixed to the toes to pass through. In using the splint it was only necessary to apply it to the under surface of the toes and to fix it not too tightly with strapping, an elastic ring, or piece of narrow bandage. It might be worn at night inside a stocking, in a slipper or loose shoe during the day, or even in a boot if the boot had room enough to contain it with comfort to the foot. With this splint much might be done to correct deformities of the toes—no severe or painful measures were required; properly applied and regularly worn it gradually brought some of the most distorted toes to the normal condition.

Dr. J. M. **Bartrina** read a paper on the Alterations in the Shape of the Urethra in Hypertrophy of the Prostate and described a new catheter for prostatic cases. He pointed out that in hypertrophy of the prostate the urethra was not strictured but its shape was altered. The prostatic urethra was enlarged and in some cases to such an extent as to be mistaken for the cavity of the bladder, but this was very exceptional. It was, however, not at all rare to find a prostatic urethra measuring several centimetres in its antero-posterior diameter. This alteration in the shape of the urethra depended on the hypertrophy of the prostate. If the middle lobe was enlarged the urethra became bent and if the lateral lobes were hypertrophied the urethra was flattened, but this flattening was always present, for the hypertrophy was never limited to the middle lobe. This opinion was also maintained by Albarran and Motz. Sometimes the lateral lobes were unequally hypertrophied and then the lumen of the urethra might have various forms and in section it might resemble a cross or an italic *f*. From these facts it was easy to interpret the cause of the difficulty of catheterism in cases of hypertrophied prostate and this cause was not the bent form of the urethra, for if it were so and the catheter were to follow the upper wall of the canal it should infallibly enter the bladder. The real cause was the flattening of the urethra and therefore the catheter for a case of hypertrophied prostate must be suited to a flattened urethra. Dr. Bartrina had had made a catheter flattened from side to side with a sharp upward turn near its apex. In practise the catheter had been a great success in prostatic cases, passing easily in cases where the greatest difficulty had been experienced with ordinary catheters, and a urethra which had only allowed the passage of a No. 14 or 16 (French) catheter would admit readily a No. 23 or 25 flattened catheter.

Professor **Cesare Ghillini** (Bologna) read a paper on the Treatment of Club-foot. He confined himself to congenital equino-varus, the commonest and the most interesting form. He was inclined to attribute this deformity to intra-uterine pressure acting on the fœtus. Club-foot was generally due to the soft parts, for the bones were only slightly deformed. Professor Ghillini then reviewed the different operative methods of treatment and expressed the opinion that club-foot was always curable whatever the degree of deformity or the age of the patient. He described his own practice. In cases seen shortly after birth manipulation was employed; later forcible manual correction; and when this failed he performed about the end of the first year of life Phelps's operation (tenotomy of the tendo Achillis and division of all the soft parts opposite the medio-tarsal articulation) and, if necessary, he opened this articulation. The orthopædic surgeon had two indications: firstly, to remove the obstacles to correction and as these were chiefly the soft parts they must be divided; and, secondly, to maintain the correction by the application of a plaster-of-Paris splint and to keep it on sufficiently long. In one case Professor Ghillini had kept a plaster-of-Paris splint on for seven months. If necessary the splint could have an aperture opposite the wound to allow of the application of dressings. The results had always been satisfactory both as to shape and to function. He was inclined to avoid all operations on the bones, for talipes equino-varus was "an affection of the muscles rather than of the bones."

Dr. R. **Harvey Reed** (Rock Springs, Wyoming, U.S.A.) read a paper on a New and Practical Method of Anchoring the Kidney. Dr. Reed made a longitudinal anterior incision immediately over the middle of the normal position of the kidney. The incision was two and a half inches long, or more if necessary, and was carried through the substance of the abdominal wall and entered the peritoneal cavity. The intestines were held aside, the small bowel being drawn to the opposite side and the colon outwards, so as to enable the operator to get at the kidney which was then brought to its normal position. Two straight needles, seven inches long, were then taken and the ends of a silkworm-gut ligature were passed through the eyes of these needles. One needle was then passed through the posterior peritoneum and the kidney and then immediately above the twelfth rib through the muscles of the back and skin. The second needle was inserted one inch from its fellow, but on the same level, and passed through the same structures. The needles having been brought out at the back were unthreaded and the suture was then tied over a piece of gauze. Care was required to see that no intestine was included within the loop of suture in the abdomen and it was also important that the suture was not tied too tightly. The abdominal wound was then closed. In about 14 days the suture was removed and in another fortnight the patient might go about. The operation was very simple and easy to perform. Permanent adhesions formed which fixed the kidney in its position. Dr. Reed had had 30 cases in which he had performed this operation and 29 of them were successful, and no deaths occurred. In the unsuccessful case the kidney became moveable some six months later and needed a further operation.

GYNÆCOLOGY.

Dr. A. **Lapthorn Smith** (Montreal) read a paper on Cancer of the Uterus. He held that the present results of treatment were extremely unsatisfactory and if any better results were ever to be obtained it must be by general practitioners recognising the condition at an early stage. The earliest symptom was irregular hæmorrhage from the uterus, especially after coitus, and especially in women who had passed the menopause. Every patient with such hæmorrhages should be examined and if the cervix was found torn it should be sutured as soon as possible, for Dr. Lapthorn Smith held that if every torn cervix were sutured within a year of the accident cancer of the cervix would not occur and that cancer of the cervix was increasing in the countries where this precaution was not taken. In his own practice every tear of the cervix was sutured as early as possible and cancer was very rare. As soon as the disease was suspected the uterus should be removed. He held that cancer was not in the least hereditary but very contagious and that when this belief was general it might be possible to do away completely with cancer.

Dr. J. L. **Faure** (Paris) read a paper on the Technique of Abdominal Hysterectomy. He maintained that the methods and details of abdominal hysterectomy must vary with the individual case and that if the surgeon did not adapt his method to the special conditions present unfortunate results might follow. Apart from cases of malignant disease, partial hysterectomy was always to be preferred to total removal of the uterus, even if it were only for the greater ease in arresting hæmorrhage. In malignant disease the whole uterus and the upper part of the vagina should be removed, if in any way possible. The vagina should not be divided until the uterus had been completely isolated from surrounding parts and especially from the ureters and this dissection could only be carried out with safety by dissecting slowly on each side from the fundus of the uterus downwards. In all other cases partial hysterectomy was sufficient. The cases divided themselves into two classes: cases of fibromata of the uterus and cases of affections of the appendages, for when these diseases and tumours of the uterine appendages were bilateral hysterectomy was often necessary. Dr. Faure laid it down as an important principle in partial hysterectomy that whenever possible it was better to separate the uterus and its annexes from their attachments from below upwards. This was very easy in the case of fibromata. If the fibroma was moveable and could be turned forwards a cut with scissors posteriorly at the level of the isthmus separated the cervix from the body and the uterus was only held by the broad ligaments. The right hand passing between the cervix and the body picked up the right broad ligament and it was clamped and divided with scissors. The uterus was then turned to the left and the left broad ligament was seized, clamped, and divided, and the uterus was thus removed in a few seconds. This was hysterectomy by "primary section of the cervix." If the fibroma was fixed by being adherent posteriorly primary section of the cervix could be performed from before backwards, and thus an operation was rendered easy which by any other method would be very difficult. If the uterus could not be drawn up and the cervix was therefore inaccessible Kelly's method was the best—that was, passing from above downwards through one broad ligament and then dividing the cervix. It was, however, especially in cases of affections of the annexes in which hysterectomy was justifiable that the method employed must be varied according to the conditions present. Where possible primary division of the cervix was the best, but if adhesions were present on one side Kelly's method should be used. If, however, extensive adhesions on both sides rendered this impossible the method Dr. Faure advocated was to make a mesial incision through the uterus from the fundus to the cervix; then each half of the cervix was divided and the broad ligaments were attacked from below upwards. These methods might sometimes be usefully combined. The chief aim should be to reach as easily as possible the isthmus of the cervix and to attack the broad ligaments from below upwards.

Neurology.

Dr. J. F. **Sutherland**, Deputy Commissioner in Lunacy for Scotland, read a paper on the Geographical Distribution of Lunacy in Scotland and Ireland (*urbs et rus*). The significance of migration and mortality under five years of age was clearly brought out. The paper was well received and the maps and diagrams illustrating it excited favourable comment. The view was put forward that so many imbeciles under five years of age being swept off by neglect, injudicious dietary, and zymotic disease in urban and city areas accounted for the vastly different ratios of lunacy prevailing in rural and urban areas. The ratio was 30 per 10,000 in the urban districts and it was as high as 90 per 10,000 in rural districts. The reverse was the case with the mortality under five years of age which was thrice as great in urban as in rural areas. The shaded maps exhibited were framed on the census of Great Britain and Ireland taken in the year 1901.

Therapeutics.

Dr. R. **Blondel** (Paris) read a paper upon the Physiological and Therapeutical Properties of Milk Serum, of which the following is an abstract. The serum of cow's milk obtained in a state of purity by rapid coagulation at a temperature of 38° C. by means of an acid and then neutralised with soda and filtered through a porcelain filter showed certain very remarkable properties which appeared hitherto to have been unnoticed, for nothing had been used for the same purposes except skimmed milk sterilised at a temperature of 100° C., the result of which was that a liquid was obtained differing but little from a simple solution of milk sugar and the salts found in milk. Serum, however, prepared in the above manner contained in addition a definite proportion of albumin and of organic ferments such as pepsin, trypsin, lipase, and glycolytic ferment and oxydases. The true oxydases, however, which had the power of striking a blue colour with tincture of guaiacum were but scanty and the oxydases most marked were the indirect oxydases which did not colour guaiacum blue except in the presence of a watery solution of oxygen. If the serum thus obtained was placed in flasks sealed up in an atmosphere of carbonic acid the action of the ferments was stopped and the fluid remained unchanged. Injection into a healthy man hypodermically in doses of 20 cubic centimetres per diem was carried out for one month without any inconvenience. The weight, however, diminished somewhat and the urine underwent important modifications, that was to say, the excretion of the urea, of uric acid, and of phosphates was considerably augmented. When administered to a gouty patient the day after an acute attack of gout within 24 hours the patient had another attack with a profuse discharge of uric acid. The effect of the injections upon the blood-pressure was to lower it markedly. Dr. Blondel then gave details of various cases of infectious fevers in which the serum had been administered at the Pitié and Charité hospitals. In these cases the injections lowered the temperature. Dr. Blondel considered that the lowering of the temperature was due to two physiological actions, that of the oxidising ferments which destroyed the toxins and that of the albumin which was injected which brought about a marked leucocytosis. Dr. Blondel had never found any disagreeable results from the injection. It was not painful but sometimes three or four hours after the injection the limb into which the serum had been injected felt cold. Sometimes, too, a light cloud of albumin was found in the urine. The simultaneous administration of 5 or 10 centigrammes of sulphate of quinine had a marked effect in increasing the power of the injection to lower the temperature. This, Dr. Blondel thought, was remarkable, for quinine alone had no effect in cases of puerperal septicæmia. To sum up, milk serum employed in this manner lowered the blood pressure very markedly and also lowered the temperature. Dr. Blondel had obtained encouraging results in various infectious diseases and more especially in cases of puerperal septicæmia. Altogether he had tried the treatment in 30 cases, including surgical cases and cases of puerperal septicæmia.

Dr. [illegible] (Paris) read a paper on the Methods of app[illegible] lue. He co[illegible] of high-f[illegible] on, brush discharge, spark discharge, and the application by means of various electrodes attached to the upper spiral of a monopolar resonator. He also mentioned brush discharge and application of the current by electrodes attached to bipolar resonators. The bipolar brush discharges he considered inefficacious and illogical in cases of pulmonary tuberculosis, for they increased the activity of tissue change. He had found them useful, however, in cases of neuralgia, rheumatism, diabetes without azoturia, and neurasthenia with loss of arterial tone.

A paper on a New Method for the Pleasant Administration of Nauseous Drugs was communicated by Mr. **Otto Maresch** (Trelleborg, Sweden). Mr. Maresch pointed out that although most branches of medicine and surgery had made enormous advances within the last 50 years yet the art of pharmacy had not advanced *pari passu*. The method of giving nauseous drugs except when they were given in capsules, which children generally found difficulty in taking, was still very much as it was in the middle of the last century. He had made various experiments and had found that many ill-tasting drugs could easily be made into an emulsion with cocoa and sugar and that their taste thereby was completely hidden. He mentioned especially bitter drugs, such as quinine, and nauseous drugs such as castor oil. His emulsion was made by a process involving quick cooling.

Dr. **Decref** (Madrid) read a paper entitled "A Contribution to the Study of the Treatment of Ataxia by the Re-educative Method." He pointed out that there were three stages in the history of this method. The first corresponded to a work published in 1877 by Dr. Godard of Paris on Chervin's treatment of stammering. Dr. Moutard Martin defined this trouble as an intermittent spasmodic condition of the phonetic apparatus and Dr. Godard accepted this definition as it explained the Chervin treatment which consisted in (1) regulating the respiration and prolonging expiration so as to allow the pronunciation of a word without interruption ; (2) in educating the phonetic apparatus by a special course of gymnastics in order to overcome the muscular rigidity so as to allow the tongue, the jaws, and the lips to assume the necessary positions ; and (3) in strengthening these actions by attention and reflection. This was the basis of all the re-educative methods. The second step corresponded to a paper Dr. Decref published in 1887 in the *Medical Review* of Madrid. The third step consisted in Dr. Fränkel's communication to the Academy of Bremen when he presented three cases of locomotor ataxia in which the incoördination had disappeared as the result of a series of exercises. Since this date others had used these methods. Dr. Decref himself had employed re-educative exercises in 25 cases of chorea and with great success. He described one case where the patient was eight years old and suffered from a very severe chorea. The movements were very violent and the child was unable to speak a word. He was much wasted, the disease had lasted six weeks, and no treatment appeared to have made any improvement. The child was treated by the re-educative method *on 30 occasions and the chorea completely disappeared, but* the wasting was as marked as ever. Later, while at a watering-place in the north of Spain pieces of a tapeworm were expelled and by suitable treatment the whole worm was removed. The average time required for the complete treatment of cases of chorea had been a month. In slight cases a fortnight had sufficed. The following was the procedure adopted : (1) a tepid spinal douche lasting for half a minute ; later, when the spasms had diminished, this might be replaced by the cold douche or the hot douche at a temperature of from 43° to 45°C. (113°F.) if there were any rheumatic complications ; (2) immediately after the douche the patient was lightly massaged all over, effleurage being employed ; (3) the patient, dressed suitably, then performed the various exercises, such as (*a*) flexion, extension, and abduction, first of one foot and then of both feet together ; (*b*) flexion of the knees and hips, abduction and adduction of the legs, and so on ; and (*c*) similar movements of the arms. All these exercises had to be guided by the operator's hands, but he should not force the limbs in the direction in which they had to go. The exercises should be performed rhythmically and to the order of the operator who counted aloud at each movement. (*d*) When the patient improved all these exercises had to be performed in the standing position. These exercises were repeated every day and the facility of their performance was soon seen to increase.

DERMATOLOGY AND SYPHILOGRAPHY.

Dr. JAY (Clermont-Ferrand) read a paper on Excision of Syphilitic Chancres. He pointed out that excision of syphilitic chancres was a hopeful method of aborting syphilis. In most of the patients upon whom he had operated careful observation for a long period of time after the operation enabled him to state that neither secondary nor tertiary syphilitic symptoms had appeared. The ulceration had appeared at the normal date after contagion and the syphilitic nature of the lesion appeared evident, both from its clinical features and from information derived from an examination of both parties. The success, therefore, of the treatment was founded upon as firm a basis of argument as it was possible to put forward Dr. Jay concluded by affirming that it was possible to eradicate syphilis by removing the early focus of the disease and so far as regarded chancres easy of access, such as those on the prepuce, he said that his motto was, "Excise and watch."

PEDIATRICS

Dr. A. L. PEYROUX (Paris) read a paper on the work of two charitable undertakings, the "Consultations de Nourrissons" and the "Gouttes de Lait" The first of these was concerned almost exclusively with breast-fed infants and had given excellent results. The second, on the other hand, was concerned almost entirely with artificial feeding and its results had been unsatisfactory, not on account of the sterilised milk itself, but on account of difficulties connected with supervision The "Gouttes de Lait" by distributing sterilised milk to mothers without at the same time making inquiries as to their home circumstances and their possible ability to suckle their infants had, according to Dr. Peyroux, done what it could to discourage breast-feeding and was therefore undeserving of support.

Dr. ERNEST DEUTSCH (Budapest) also read a paper on the "Gouttes de Lait." He said that women who were insufficiently fed could not suckle their children properly and therefore the relief ought to commence with the distribution of milk and tickets for soup-kitchens. If the infant did not gain in weight artificial feeding ought to be combined with suckling. When the mother had no milk the alternative was to supply pasteurised milk in bottles, each bottle containing the quantity to be used at a time. A medical man ought to be attached to the "Gouttes de Lait" and instruction ought to be given to mothers by the holding of meetings and the distribution of pamphlets.

Dr. ALBERT JOSIAS and Dr. JEAN CH. ROUX (Paris) communicated a paper on the Treatment of Tuberculosis in Children by Meat Juice and Raw Meat. This system was followed in the case of 46 patients who took 150 grammes of meat juice and 100 grammes of raw meat every day. Of these patients 16 suffered from tuberculous peritonitis and meningitis, acute tuberculosis, and Pott's disease. The remaining 30 were the subjects of pulmonary phthisis and of these 13 either recovered or were greatly improved and 14 *died.*

Dr. F. J. POYNTON (London) read a paper on a Microbic Agent considered as the Connecting Link between Chorea, Endocarditis, and Articular Rheumatism in Childhood. He said that investigations chiefly on a statistical basis made by H. Roger in 1866 and by many subsequent writers had proved the close association of chorea and rheumatism. He and Dr. Alexander Paine had produced chorea experimentally in a rabbit by inoculating it with the diplococcus of rheumatic fever and they had found the diplococcus in the rabbit's pia mater and the endothelium of the cortical capillary vessels. They had also found micrococci in the mitral valve, the cerebral cortex, and the pia mater in a fatal case of human chorea.

Dr. PATRICIO BOROBIO DIAZ (Saragossa) described 15 cases in which Surgical Anæsthesia had been produced in children by intra-spinal injections of a centigramme (one-seventh of a grain) of cocaine. Two of the operations were for urethral fistula ; the others were performed on the lower extremity and included a Pirogoff's amputation for tuberculosis of the tarsus.

Dr JOSE VIEDEN PORTELLO (Valencia) read a paper on the Treatment of Purulent Ophthalmia in the Newly-born. He recommended the local application of solutions of protargol of the strength of from 2 to 5 per cent. twice a day. In the intervals, with the aid of his new elevating irrigator, the eyes were to be bathed two or three times in the 24 hours with warm boric acid lotion which might contain a small quantity of solution of formalin having a strength of 1 in 2000. A little vaseline containing 2 per cent. of iodoform precipitated by ether should also be applied every four hours or more frequently. By this means a cure might be effected in from eight to 15 days. Nitrate of silver and solutions of corrosive sublimate should on no account be employed while the inflammation was active.

Dr. LUIS FATAS Y MONTES (Madrid) read a paper on Child Mortality in Madrid He said that during the last five years the average annual birth-rate of Spain was 34 50 per 1000, while that of Madrid was 32 69 per 1000. During the same period the average annual death-rate of Spain was 28·79 per 1000, while that of Madrid was 31·43 per 1000, a proportion which compared unfavourably with the death-rate of all the other European capitals. The child mortality per annum was very high—457 16 per 1000; as everywhere else, the mortality was in inverse ratio to the age, being 49 40 per cent. under one year, 38·52 per cent. from one to five years, 8 72 per cent from five to 10 years, and 3 35 per cent. from 10 to 15 years. Of 10 children born about six reached the fifth year. One year's statistics showed that the death-rate of illegitimate children was lower than that of legitimate children, an anomaly which might be explained by the fact that many of the former were put out to nurse and for that purpose were sent away from the city as soon as they were born. There was no discoverable relation between infant mortality and density of population. Of the deaths 25 66 per cent. were due to respiratory diseases, 20 21 per cent. to nervous diseases, and 26·70 per cent. to infectious diseases, including *tuberculosis and syphilis. In Madrid the proportion* of still-births was higher among illegitimate children than among legitimate; in Barcelona 25 per cent of the illegitimate children were stillborn Dr Fatas y Montes made a variety of recommendations for the improvement of the existing state of things, including prohibition of marriages of persons suffering from transmissible diseases, medical inspection of [illegible] spitals for children,

[illegible] aper on the Serum Treatment of Diphtheria with special reference to the use of Roux s serum, which, he said contained 1000 antitoxin units in five cubic centimetres and had been found to remain active for a long time—even for 18 months or two years It ought not however to be kept longer than two years Serum should be injected as soon as possible in all cases known or presumed to be diphtheria, without waiting for the completion of a bacteriological examination It was better to make 100 unnecessary injections than one that was too late The quantity injected in ordinary circumstances varied from five cubic centimetres for infants aged only a few weeks or months to 20 cubic centimetres for children above ten years Before the employment of serum the case mortality in diphtheria was 50 per cent, but it had now been reduced to 12 or 15 per cent *Injected as a prophylactic Roux's serum conferred* an immunity lasting three or four weeks The injections caused exanthematous eruptions on the skin in more than 16 per cent of the cases

Dr FRANCISCO CRIADO Y AGUILAR (Madrid) read a paper on the Pathology and Treatment of Pseudo hypertrophic Paralysis He believed that the increase in the volume of the muscles was due to hyperæmia of the spinal cord The treatment consisted of rest in bed, milk diet and counter irritation to the spine, baths and massage were injurious

Dr LOPE CARRALERO (Madrid) read a paper on Coryza in Suckling Infants as an Early Sign of Hereditary Syphilis

OTOLOGY

Dr H J L STRUYSCHEN (Breda) read a paper on Acouometry, the object being the determination of the lower limit of loudness of sound perceptible in a case of deafness The principle involved was the measurement of the decreasing amplitude of a vibrating tuning fork and the observation of the moment when the sound was no longer audible The decrease of amplitude being measured in micro millimetres by Gradenigo's method it became possible to calculate the amplitude (and consequently the loudness of the sound produced) at a given instant.

Professor E SCHMIEGELOW (Copenhagen) read a paper on the Causes of Deaf Mutism Of these the most important was loss of hearing, either total or partial. Total loss of hearing either congenital or supervening before the age of eight years brought about deaf mutism in most cases but not in all With respect to partial loss of hearing Professor Schmiegelow considered that children who could not hear ordinary conversation at a greater distance than ten inches would become deaf mutes

Dr A CASTEX (Paris) also read a paper on the causes of Deaf Mutism, prefacing it by an eulogy of Ponce de Leon a celebrated instructor of deaf mutes in Spain in the sixteenth century Congenital deaf mutism was most often met with in mountainous countries and had a tendency to affect male children born of consanguineous parents Heredity showed itself as between grandparents and grandchildren rather than as between parents and children Syphilis tuberculosis, rickets alcoholism in the ancestry, illness of or accidents to the mother during pregnancy, and lesions of the labyrinth, brain, and medulla oblongata were important predisposing causes Some of the most energetic factors in the production of acquired deaf mutism were affections of the brain and meninges measles scarlet fever, and diphtheria

Dr MARCEL LERMOYEZ (Paris) read a paper on the After treatment of Operations on the Ear, with especial reference to mastoid trephining

LEGAL MEDICINE AND TOXICOLOGY

Dr FRANCISCO CARBONELL Y SOLES (Barcelona) read a paper on the use of Crystallography in the Identification of Poisonous Alkaloids Chloride of sodium normally crystallises in cubes, but when crystallised from solutions containing very small quantities of alkaloids it assumed a variety of forms by observing which he said that the alkaloids in question might be recognised

Dr DIO A VALDIVIESO Y PRIETO read a paper recommending that the Transmission of Venereal Disease should be made a statutory offence, without regard to the sex or social position of the culprit, and that the penalty should be two years imprisonment together with liability for all medical expenses incurred and for compensation to the injured party In the event of the culprit being unable to make these payments an additional term of imprisonment should be imposed Brothel keepers (*las dueñas*) should be liable to fine and imprisonment in the event of the women in their establishments (*las pupilas*) failing to make the requisite payments

OPHTHALMOLOGY

Dr JUAN SANTOS FERNANDEZ (Havana) read a paper on Eye Disease in Cuba The only unusual disease of the eye mentioned by him was cequera an endemic purulent ophthalmia which sometimes became epidemic and was carried from one person to another by a small fly It seemed to be produced by the bacillus of Weeks and the diplococcus of Mora With respect to the effect of tobacco on the eye he was decidedly of opinion that tobacco had been blamed for giving rise to morbid conditions which were really due to alcohol, but he admitted that many medical men in the island did not hold this view Myopia was rare, especially in negroes but the majority of the inhabitants of the island were hypermetropic and the use of spectacles was increasing

Dr FERNANDEZ also read a paper on the Lacrymal Canal in the Negro being a record of comparative observations made on 24 dissecting room subjects of whom 15 were whites and nine were negroes He found that in whites the nasal canal was long and somewhat tortuous, it was therefore liable to stricture and other disorders In the negro on *the other hand, the nasal canal was wide and straight in* consequence of which negroes were less liable than whites to stricture and other complications affecting the lacrymal sac and lacrymal canal

BIRMINGHAM

(FROM OUR OWN CORRESPONDENT)

Women's Hospital

THE annual meeting of the supporters of this institution has recently been held and the report read thereat shows that the number of new cases seen in the out-patient department was 3379 being an increase of 94 as compared with last year The total number of new and old cases treated during the year was 18 078 being 904 more than last year On the other hand, there were 14 less patients admitted to the in patient department the total number being 426 The total number of operations was 412, among these were 234 cases involving abdominal section Of these three patients died, giving a death rate of 1 28 per cent, as compared with 4 2 per cent on 213 operations in 1901 From the founding of the hospital to Dec 31st 1901, there have been 3376 operations and of these patients 215 died giving a death rate of 6 36 per cent. For the five years 1897 to 1901 inclusive there were 882 operations and 41 of these patients died giving a death rate of 4 64 per cent. Allusion was made to the subject of the new hospital for which funds are now being collected It is intended that there shall be 40 beds and that the building shall be easy of access both to the medical staff and to the convalescent home About £40 000 will be required for the purchase of the freehold site and for building and equipping the new hospital Towards this amount a sum of over £26 000 has been given or promised and great efforts are being made to secure the balance

Ear and Throat Hospital

The annual meeting of the friends and supporters of this hospital was also held recently During the year 1192 in patients were treated as compared with 1172 in the previous year The number of out patients was 8122, being 1120 more than in 1901 Here, also, there is an urgent cry for extension but the response to the appeal for funds has so far not been very encouraging only £1300 out of the necessary £8000 having been promised. This hospital has had some considerable losses during the year Mr F Marsh and Dr F W Foxcroft who has been appointed aural surgeon and laryngologist at the General Hospital have both resigned their connexion with the hospital Moreover, it has lost by death the services of Mr G Panton, F.R.S. Edin., for a number of years its honorary secretary. Mr. Panton, who was almost up to the time of his death secretary in Birmingham to the Scottish Provident Association, had rendered most valuable service to the hospital. His methods and ideals had by no means always been such as to commend themselves to the members of the medical profession, but, on the other hand, it must be admitted that he found the hospital a small and comparatively obscure charity and left it in a much more prominent position.

The General Hospital.

The growth in the efficiency of provincial hospitals and, it may also be added, in the expensiveness of their management, is well exemplified by a comparison between the resident staff of this institution 20 years ago and at the present day, it being remembered that the number of beds has been but little increased during that period. 20 years ago there were only three qualified residents attached to the institution—resident medical and surgical officers and pathologist. The last-named official was responsible for the administration of all the anæsthetics—a somewhat singular combination of duties—and he had also the laborious task of compiling the annual tables of statistics for the hospital reports. At the present day there are a resident surgical officer with four house surgeons under him, a resident medical officer with three house physicians, a pathologist—who no longer gives anæsthetics, for two special officers are appointed for that purpose—and now a fresh resident post has been created in the shape of a house surgeon in charge of the special departments of the hospital, obstetric, ophthalmic, and oral. This hospital has recently lost one of the oldest members of its committee in the person of Mr. A. A. Ellis of King's Norton. Mr. Ellis had never taken much part in the public work of the city but had served the General Hospital with untiring faithfulness for many years and will be much missed by all connected with it.

The Medical Officership of Health.

The council has now decided upon the terms of this appointment which I observe is advertised in your advertisement columns. At the meeting at which the report of the health committee on the subject was discussed some truly original remarks were forthcoming from the wise men of the city. According to the daily paper one councillor's speech appears to have consisted of the remark—"Give him a thousand a year—Lord 'a mercy!" Another suggested that the work of the medical officer of health in the city was mainly of a routine character, which shows a fine ignorance of the actual state of affairs, whilst another sapient worthy thought the salary so enormous that there was a risk of tempting some man whose reputation had been made and who would be content to come to Birmingham to rest upon his laurels. Reason, however, prevailed, and the recommendation that £1000 per annum should be offered was approved by an overwhelming majority. It is probable that the council will have no lack of candidates from amongst whom to make a choice. It is to be hoped that its selection may be a wise one. A strong man, possessed of commonsense and tact, is badly needed, and if possible he should be a man whose selection will commend itself to the general practitioners of the district, for should this be so the possibilities of friction will be much decreased.

The University.

The report of the visitor and inspector of the General Medical Council on the final examination of the University for medical and surgical degrees held last June has recently been made public and by an excellent new rule of the Council copies have been sent to all the examiners in the subjects of the final. The report is one with which the University has every reason to be well satisfied. It speaks of the examination as "a practical examination of a high standard, well planned and well carried out." The practical examination in pathology and the practical examination in forensic medicine are very highly spoken of. With respect to the latter the report states that, "Judging from the description of the practical examination which we have given from the information furnished to us and from the written work of the six candidates whose papers we have read, we should say that this examination, as far as our experience goes, is unique of its kind and that it deserves high commendation." A few suggestions for the future were made by the visitor and inspector and according to the report of the Examination Committee of the General Medical Council on the reply of the University, "the authorities of the University have wisely recognised the value of the friendly criticism of the inspector and visitor, and have, in the view of this committee, met them sensibly and well." It must be a source of great satisfaction to all friends of this young institution to find it come out so well from its first inspection. Since I last wrote two reading- and writing-rooms for the use of the medical students only have been opened in the University buildings. These rooms, which have been very comfortably furnished, will supply a want which has long been felt and will, it is hoped and believed, greatly add to the comfort of the medical students who have in the past had no separate accommodation of their own.

May 12th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Opening of the Johnston Laboratories at University College, Liverpool.

THE Right Hon. Walter Long, M.P., the President of the Local Government Board, formally opened on May 9th the new laboratories, the gift of Mr. William Johnston. A description of the laboratories appeared in THE LANCET of May 9th, p. 1338. The opening ceremony took place in the Arts theatre of University College in the presence of a distinguished company, including prominent citizens of Liverpool, many foreign guests, and the professors and lecturers of the College in academic costume. Mr. E. K. Muspratt, in the absence of the Earl of Derby, K.G., presided and amongst those on the platform, besides Mr. Walter Long, were the Lord Mayor, Mr. William Johnston (the donor of the laboratories), Sir Alfred L. Jones, K.C.M.G., Principal Dale, Sir Michael Foster, K.C.B., M.P., Professor G. Sims Woodhead, Professor F. Gotch, Professor T. Clifford Allbutt, Dr. Ravenal (Philadelphia), Professor Weigert (Frankfort), Professor Blanchard (Paris), Professor Perroncito (Italy), Professor Nocard (Paris), Professor Eulenburg (Berlin), Professor Uhlworm, Professor von Hausemann, and Dr. Sleegmann (Holland). Prior to the opening speech of Mr. Long, Principal Dale read a letter from Lord Derby, the President of the College, in which he expressed great regret at his unavoidable absence from the opening ceremony, as it would have given him great pleasure to welcome the many distinguished foreign visitors. Mr. Muspratt (the chairman) said that he had received a number of telegrams from various parts of Germany expressing good wishes for the success of the work of the new laboratories. That gathering had assembled to witness the opening of the laboratories in which a large amount of original research would be carried on and which they owed to the munificence of Mr. William Johnston who had for many years taken a deep interest in the progress of medical science and had seen the need of devoting a large amount of his means to the promotion of original research in medicine. It was with that view that Mr. Johnston approached Professor R. W. Boyce who saw the means by which Mr. Johnston could promote the object which he had nearest at heart. They had also to welcome Mr. Long, a representative of His Majesty's Government and the head of the Local Government Department. He hoped Mr. Long's presence there was an indication of the increased interest which the Government took in the progress of science. Nearly all the Government departments for the last 50 years had been obliged to seek the assistance of scientific men and though they had availed themselves of the services of these men they had thought little of the necessity of training up with the increase of civilisation a large number of men of high scientific attainments. The training of such men could not be conducted in classes of science and art alone but in a large institution such as University College, which he trusted in the near future would become a university. In the laboratories which Mr. Long was about to open that afternoon was a department of bio-chemistry. For a number of years Germany had had a large number of professors of that one science. Chemistry really lay at the root of many other sciences. It was more than 50 years since Baron Liebig first showed the world that chemistry could be of great assistance to physiology and afterwards to pathology. Bio-chemistry had developed into a special science. It was known for a long time in Germany as physiological chemistry but it was now extended and was called bio-chemistry. It had practically to do with the chemistry of life and of living matter The department in the new laboratories of experimental medicine was a new development of medical research and the first object of these experiments would be undertaken for the study of cancer He hoped Mr Long would carry away with him a feeling that if they were to have scientific men in the future to work in the Government departments it was necessary that they should do their best to promote original scientific research Mr William Johnston, who was very heartily received, said that it gave him great pleasure to tender for the acceptance of the council the laboratories which Mr Long had so kindly consented to open It had afforded him much gratification to be associated with the laboratories, because from his early days he had taken the deepest interest in medicine and in medical research *He trusted that the laboratories would prove successful,* as he was sure they would be, considering the eminent men in whose charge they were placed, and he further hoped that they would contribute to placing the medical school of *their new university in the foremost rank of scientific* schools He asked Mr Long to declare the laboratories open Mr Walter Long, who was very warmly received, said that there could not be any doubt that there were a great need and a very widespread demand for laboratories such as the one presented by Mr Johnston He did not believe that there was any need to impress upon his colleagues in the Government the importance of such work as would be performed in those laboratories It was appreciated by them as it was appreciated all the world over Members of governments were not altogether in easy positions He did not refer to their political party life or to their conflicts in the House of Commons but to the inner side of their life As President of the Local Government Board what could be pleasanter or easier for him than to meet the chairman in his suggestion more than half way and to assure him that the resources of the State should be exhausted in days to come in order to do their duty to science, and especially to medical science ? Members of the Government had to act not separately but conjointly and so long as he had the honour to occupy his present position he would do his best to secure on behalf of the Government of the day the utmost assistance which could be given to the advancement of science in all parts of the country How close, it seemed to him, was the connexion between the development of science—and especially that form of it known as preventive medicine—and commerce for which this great country was so justly famous, and in the city of Liverpool there was especial and striking evidence of this union The School of Tropical Medicine in Liverpool had already been productive of conferences of the greatest possible value, not only between members of the school and people engaged in commerce, but conferences which had drawn to them and included the presence of distinguished men from our colonies and from foreign countries That union was not only striking in itself but had been pro*ductive of great and valuable results Then he came to* a question which closely touched the department with which he was concerned It had always been the object of that department, while imposing regulations which had for their object the prevention of the spread of disease at the same time to do as little as possible to injure the trade of this country and the trade of the world The work that would be done in these laboratories would be of the greatest advantage and of the most inestimable benefit to the country as a whole. *He admired the munificence of the citizens of Liver*pool. The permanent record of their work was in the splendid buildings which existed for the purpose of research and the schools and scholarships which they had founded for this most beneficent work Not only had they contributed £200 000 to the university fund but they had a notable instance in the fact that the city was willing to be rated for the purpose of maintaining university training in this direction. One felt truly for those engaged in this great work Let them try to realise what were the sufferings of the men in the time of Wellington and to contrast those with the possibilities for the relief of pain in the war just concluded The work to be done in the new laboratories would tend towards the relief of pain and of human suffering and they owed much to Mr Johnston and to the munificence of other benefactors whose large-heartedness had enabled such a work to be successfully carried on All knew what terrible suffering resulted from cancer There had been startling discoveries made in connexion with the more common diseases, such as diphtheria and typhoid fever The investigation of cancer was one of the great works which the munificence of Mr Johnston would enable them to carry on in those laboratories In declaring the laboratories open Mr Long commended the donor's munificence in saying that "Much has been done', "There is still a wide field", "Yet much remains to conquer still"; and "Peace hath her victories no less renowned than war' That might rightly be the motto for large hearted citizens like Mr Johnston *Might his beneficence be followed by great* and triumphant victories in the field of human life Principal Dale moved —

> That this meeting of members and friends of University College expresses its sincere gratitude to Mr William Johnston for the munificence which has enriched the University of Liverpool for the work of medical research and to Mr Walter Long for his kindness in taking part in the inaugural ceremony

Principal Dale said that the laboratories were but a part of Mr Johnston's gift to the University He had founded and endowed the chair of bio chemistry to which Professor Moore had been appointed Mr Johnston had also founded and endowed three fellowships for the purpose of medical research The motion was seconded by Professor Gotch The Lord Mayor, as representing the citizens, and Sir Alfred Jones, as representing commerce, cordially supported the motion, which was carried with acclamation The assembly afterwards visited the new laboratories

Banquet at the Adelphi Hotel. Symposium at the Medical Society

In the evening Mr William Johnston entertained a distinguished company to dinner at the Adelphi Hotel Covers were laid for 140 gentlemen. Mr Johnston presided, having on his right Mr Walter Long, M P, and on his left the Lord Mayor of Liverpool Other distinguished guests included Sir Michael Foster, M P, Professor Blanchard, Professor Perroncito, Professor Armstrong, Professor Gotch, Professor Weigert, Professor Ravenal, Professor T. Clifford Allbutt, Professor Schafer, Professor Hansemann, Professor Bottagi Professor S Delépine, Professor Nocard, Professor Boyce, Professor R Ross, C B, Professor Zimmermann, Professor Eulenburg, Sir Alfred Jones, Sir John Brunner, Bart, M P, Sir William M Banks, and Dr A. S F Grunbaum The chairman submitted the toasts of the King and Queen, which were duly honoured The Lord Mayor proposed the toast of "The President of the Local Government Board' in an able speech Mr Walter Long, in reply, said he was rejoiced to see that on the present occasion they had the presence not only of many of their own leading scientists but some of the most distinguished *savants* in Europe Sir Alfred Jones submitted the toast of "Commerce and Scientific Research," which was replied to by Sir Michael Foster in a witty speech He said that in modern science Liverpool took a leading place He referred to the close and cordial relationship which existed between science and commerce and expressed confidence *that in this* relation, so far as science was concerned, she would never seek to divorce herself from commerce Professor Armstrong also responded to the toast. The toast of "Our Foreign Guests" proposed by Sir John Brunner, Bart, was responded to by Professor Ravenal, Professor Blanchard, Professor Weigert and Professor Perroncito —Mr Rushton Parker, the President of the Liverpool Medical Institution, received 140 members and foreign guests at a symposium at the institution in honour of the opening of the laboratories on Monday night

The New Liverpool University

The feeling was expressed at the meeting of the court of governors of University College held on May 2nd that there was some ground for hope that the charter constituting the new university might possibly be issued at the beginning of July If that took place the next step would be to pass through Parliament an Act transferring the property of University College to the University of Liverpool A Bill for that purpose was read a second time in the House of Lords a week ago, but it could not further proceed until the charter was granted Assuming that all goes well the court of governors anticipated that the University of Liverpool would be able *to inaugurate* its career on Oct 1st next.

May 12th

THE CANCER RESEARCH FUND —The sum of £1000 has been received from Mr Henry Louis Florence by the honorary treasurer of the Cancer Research Fund under the direction of the Royal Colleges of Physicians of London and Surgeons of England

WALES AND WESTERN COUNTIES NOTES.

(From our own Correspondents.)

Proposed Incorporation of Merthyr Tydvil.

It is remarkable that among the 22 urban districts of Glamorganshire, where there is an aggregate population of three-quarters of a million, there are only two county boroughs (Cardiff and Swansea) and only three municipal boroughs (Aberavon, Cowbridge, and Neath), these three towns having a combined population of only 25,000 persons. It is the more remarkable because there are two districts (Rhondda and Merthyr) each with a population sufficiently large to qualify them as county boroughs and there are three towns (Aberdare, Mountain Ash, and Pontypridd) the population in each of which is either over 40,000 or approaching that number. As a first step towards altering this condition a prolonged inquiry extending over nine days has just been held at Merthyr by the Hon. Everard Fielding, a commissioner appointed by the Privy Council to hear evidence for and against a petition which had been presented by the district council praying that a charter of incorporation should be granted to the town and parish of Merthyr. Among the inhabitants there appears to be a very general desire to obtain the charter, the opposition coming almost entirely from the large employers of labour such as Messrs. Guest, Keen, and Nettlefolds who own the great Dowlais works, from the railway companies, and from the Glamorgan County Council, this last-named authority very naturally being loth to lose a large portion of its rateable value. The population of Merthyr is about 70,000, the rateable value is £260,000, and it has an area of some 12,000 acres, so that the arguments in favour of incorporation are strong. It is of interest to record the opinion expressed by Mr. C. Neve Cresswell who held a similar inquiry in 1897 on behalf of the Privy Council. He said that he did not desire to hear any arguments as to the advantages of incorporation, for his mind had been made up for many years as to the obvious advantages of a municipal as compared with other forms of administration. With regard to the town of Merthyr itself he said that he had been about the town and had seen quite sufficient to satisfy himself that the present system of government was not sufficient for the proper government of the place. That a vigorous local government is needed in Merthyr at the present time is evident from a statement made to the commissioner in the last inquiry by Mr. D. J. Thomas, the medical officer of health, with regard to the housing of the workpeople in the town. He said that in the past two years 497 houses, or 3·5 per cent. of all the houses in the parish, had been represented as unfit for habitation and that 255 of these had been closed and 150 demolished.

Tobacco Poisoning.

Instances of fatal poisoning by tobacco are sufficiently rare to warrant the recording of a case at Tredegar in Monmouthshire. A boy, 15 years of age, who had been for some time in the habit of chewing tobacco and who even took it to bed with him, became ill on the evening of May 5th, when he was found by Mr. Isaac Crawford, the colliery surgeon, unconscious and almost pulseless. In spite of injections of strychnine and stimulants the patient died on the following day. At the inquest which was subsequently held Mr. Crawford stated that tobacco chewing and smoking were largely practised by the boys of the district and that 14 years ago a boy of about the same age met with his death in Tredegar from tobacco poisoning.

The Treatment of Tramps.

The large increase in the number of vagrants is now matter for discussion all over the country and at a conference of the Poor-law guardians of South Wales and Monmouthshire held at Carmarthen on May 7th the subject was very exhaustively dealt with. Mr. A. F. Vulliamy, clerk to the guardians of the Ipswich Union, maintained that vagrant wards should not be provided by the local Poor-law authority but by the nation and that they should only be situated at a reasonable day's march from one another, the professional tramp being provided with a pass ticket denoting the only places at which he would be allowed to stay the night and any deviation from the route given should render him liable to imprisonment or to be sent to a labour colony. Among the members of the conference there was a pretty general consensus of opinion that the children of habitual tramps should be taken away from them, while a Cardiff guardian pointed out that the Employers' Liability Act and the Compensation Act made it much more difficult for a man 45 years of age with a few grey hairs to obtain employment.

Porthcawl Rest.

The Porthcawl Rest, which has now been established as a convalescent home for more than 20 years, is one of the best-managed institutions in South Wales and is doing a vast amount of good. At the annual meeting of the subscribers held on May 8th it was stated that the daily cost of maintenance per head had been reduced to 1*s.* from 1*s.* 6*d.* in the previous year, when the expenditure had exceeded the income by a considerable sum.

Pembrokeshire County Council.

At the annual meeting of the Pembrokeshire County Council held on May 5th Mr. George Griffith, M.R.C.P. Edin., M.R.C.S. Eng., J.P., was elected chairman.

(From our own Correspondents.)

The King's Visit to Edinburgh.

Edinburgh—and, for the matter of that, all Scotland—is fervent with loyalty and pride at the visit of the King. To your readers, perhaps, the most interesting ceremony of the visit was that of May 13th, when His Majesty opened the newly built Colinton Mains Hospital. The hospital, which is situated about four miles from Edinburgh, is intended for the reception of cases of infectious disease and stands on a site of some 130 acres. The architect is Mr. Morham of Edinburgh. Accommodation is provided for 600 patients and 150 nurses and the total cost of the buildings was £350,000. The King was received by Lord Rosebery, the Lord Provosts of Edinburgh, Glasgow, and Dundee, and Mr. Lang Todd, Convener of the Edinburgh Public Health Committee. When their Majesties arrived Mr. Lang Todd gave a short history of the institution of the buildings, and concluded by asking the King to declare the hospital open. His Majesty, in reply, congratulated the corporation of Edinburgh and mentioned the pleasure that he and the Queen felt in their visit and that the visit had taken place at a time to enable them to open the hospital. The King having formally opened the hospital the Queen planted an English elm and His Majesty followed suit by planting a Scottish elm. Their Majesties then returned to Dalkeith.

The Prevention of Consumption.

The second general meeting of the Glasgow and District Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis was held on May 6th, when Lord Inverclyde, in the unavoidable absence of the Lord Provost, presided. The council in the report submitted to the meeting showed that considerable progress had been made towards the attainment of the objects of the association—the prevention of consumption by means of the education of the public regarding its prevalence, nature, and diffusion and the provision of suitable treatment for those who suffer from it. Among the various methods adopted—and it is believed with a considerable measure of success—have been the distribution among the working classes of over 60,000 pamphlets prepared and issued by the association, the holding of public meetings in various districts of the city, and negotiating with public companies and bodies to act upon, or to obtain if necessary, compulsory powers for the suppression of indiscriminate expectoration in public places or conveyances. Action taken in this connexion led to the enforcing of the by-law regulating the conduct of the Glasgow corporation cars, with the result that several offenders were prosecuted. A great part of the work of the branch has been in connexion with the proposed sanatorium. It is now formally announced that the small estate of Bellefield, near Lanark, consisting of about 27 acres has been acquired for the purpose. The council meantime is considering plans for the erection of pavilions and the reconstruction of the Mansion House, which when completed will provide accommodation for the treatment of 60 patients. It is intended in the meantime that the sanatorium should be set apart for male patients, because there is already in existence, in connexion with Quarrier's Homes, a sanatorium for female patients. This arrangement will thus prevent at present any overlapping of good work. A fund for the erection of this sanatorium has been instituted and the promised contributions to date amount to over £3600. Lady Maxwell of Calderwood has also given for the purposes of the branch certain ground extending to about four acres, as also three cottages, all situated in the village of Maxwelltown, near East Kilbride, the income from which meanwhile is being applied to the general purposes of the branch. The total membership now amounts to 622, showing an increase of 166 for the past year.

Advanced Cases of Pulmonary Tuberculosis.

It is generally felt that the advanced cases of pulmonary tuberculosis among the working class as distinguished from the pauper class ought to have some provision made for them. This is required whether the matter is regarded from the point of view of the individual patient or from the point of view of public health. At the present time the managers of the general hospitals do not consider it to be their duty to admit such cases into their general wards—a position which is quite tenable whether we consider the welfare of the patients generally treated in these wards or the welfare of those suffering from advanced pulmonary tuberculosis where treatment is desired. Further the managers of these general hospitals cannot see their way, on account of the great demand made on their space, to set apart wards for the special treatment of these cases nor will the public health authorities undertake the duty of taking care of even those very advanced cases which are presumably acting as centres of infection. Reference is here made to others than the pauper class which should, and actually do, come under the care of the parish council. Much credit is due to Dr. J. W. Allan, late superintendent of the Belvidere Fever Hospital and now physician to the Royal Infirmary, for keeping this aspect of the question constantly before the public. It is to be hoped that his efforts will carry with them the success which they deserve and that his suggestion made in a letter to the editor of the *Glasgow Herald* of May 6th for the erection and equipment of a hospital for the treatment of such cases will get the necessary support. The state of affairs referred to is one recognised by every practitioner in the city and if rectified would diminish to a very marked extent not only the misery caused by the disease but its widespread dissemination.

Lunacy and Alcoholic Excess in Glasgow.

The Glasgow Lunacy District Board has authorised a committee to consider the annual reports of the medical superintendents of the Glasgow district asylums at Woodilee and Gartloch with reference to the number of patients admitted to both asylums during the year ended May 15th, 1902, as the direct result of alcoholic excess. Particulars of each case, including also the cases treated in the observation wards of Barnhill poorhouse from the same cause, have been obtained and a statistical summary of the whole has been compiled. From this it appears that during the 12 months 565 persons were admitted to the two asylums as insane and 213 were admitted to the observation wards of the poorhouse as cases of incipient insanity. Of this number no fewer than 259, or 33 per cent., were found to have become chargeable to the parish through alcoholic indulgence. The alcoholic subjects admitted to the poorhouse numbered 103, of whom 12 died, eight were admitted to the asylums, and 74 recovered.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Congenital Partial Intestinal Occlusion.

M. BŒCKEL at the meeting of the Academy of Medicine held on April 14th read an account of the case of a child, aged 18 months, who within six weeks after birth showed evident signs of intestinal obstruction with considerable meteorism. The introduction of tubes into both the rectum and the stomach as well as puncture of the intestine having given no results laparotomy was performed. There was found to be an enormous volvulus of the sigmoid flexure. This portion of the gut was resected and the two extremities were joined together. The abdomen was then closed and the patient rapidly recovered. M. Bœckel considered that the case was one of intestinal occlusion commencing during intra-uterine life and due to twisting of the sigmoid flexure, the condition being aided by an abnormal development of the mesocolon.

Researches into the Nature of Nephro-toxins.

M. Bierry laid before the Academy of Sciences on April 6th a paper upon Nephro-toxins. He referred to his previous work on the subject in which he had found that substances which were nephro-toxic for the dog could be produced in the blood of rabbits which had received an intraperitoneal injection of the pounded kidney of the dog. He had also found that properties which were nephro-toxic for the dog could be produced in the blood of rabbits into which had been injected simple nucleo-albumins derived from the kidneys of dogs. If a dog from 12 to 15 kilogrammes in weight received an injection of between 20 and 25 cubic centimetres of the blood of a rabbit which had been thus injected the dog showed on the third day albuminuria which increased up to the tenth or fifteenth day. On comparing the effects of the blood as a whole, of the fibrin, of the serum, and of the corpuscles he was enabled to state that the last two were the most poisonous. It would therefore appear that a nephro-toxin is a leucocyte poison. The urine of dogs which has been made albuminuric by this method contains in addition to serin and globulin certain albumoses, but never contains glucosazone.

The Relations between Acromegaly and Giantism as exemplified by the Post-mortem Examination of the Giant Constantine.

At the meeting of the Hospitals Medical Society held on May 8th M. Dufrane, M. Launois, and M. Pierre Roy showed the society certain portions of the skeleton of the giant Constantine who died in the Mons Hospital from septicæmia following a double amputation of the legs for symmetrical gangrene. The cranium showed the deformities characteristic of acromegaly. Prognathism of the lower jaw was very marked, while the sella turcica was much dilated and the pituitary body was larger than a walnut. The inferior extremities were disproportionately long as regards the trunk. The lower epiphysis of the femur and the upper epiphysis of the humerus had not united, though Constantine was 29 years of age when he died. These two abnormalities, taken in conjunction with the atrophy of the genital organs which existed, are typical of the "infantile giantism" described by M. Launois and M. Pierre Roy. But whereas in the case of Constantine the long bones continued to grow in length (*hyperostéogénèse enchondrale*) the bones of the [illegible] of infantile type and acromegaly (the two coexisted in Constantine's case) resolves the problem of the relations between acromegaly and giantism. It can now be affirmed that if all giants are not acromegalic *in esse*, yet at least all of them are so *in posse*.

The International Congress of Tuberculosis.

Last week a meeting was held in Paris of the committee of the International Congress of Tuberculosis. The delegates for the chief countries were—for Germany, M. von Leyden; for England, Dr. Hillier; for Austria, M. von Schraeder; for Belgium, M. Dewes; for Denmark, M. Roerdan; for Spain, M. Espina y Capo; for Norway, M. Holmoe; for Portugal, M. de Lancastre; for Russia, M. Blumenthal; for Switzerland, M. Schmitt; and for France, Dr. Brouardel. The various delegates described the steps as to tuberculosis which had been undertaken in their respective countries. Visits were paid to the Ormesson Hospital, where veritable miracles in the way of recoveries take place under the care of Dr. Petit and Sister Candide, and to the Calmette Dispensary at Lille. Without going into all the questions raised it may be said that the foreign delegates with M. von Leyden at their head were unanimous in praising the results which have already been attained in France. The effects of the ideas put forward by M. Albert Robin at his well-known conference some two months ago are already visible and the theory of the "barrack sanatorium," against which the famous French *savant* argued so energetically, has given place to more rational, more economical, and more efficacious measures.

May 13th.

UNIVERSITY OF LONDON: FACULTY OF MEDICINE.—A meeting of the Faculty of Medicine of the University of London will be held at South Kensington at 5 P.M. on Friday, May 22nd. The Faculty will consider a report recently rendered to the Senate by the Board of Studies in Dentistry with regard to the establishment of special degrees in dental surgery, together with proposed regulations for the curriculum of study and for examinations in this subject. A minority report has been submitted to the Senate and will also come under the consideration of the Faculty.

Medical News.

University of Cambridge.—At the third examination for medical and surgical degrees, Easter term, the following candidates were successful :—

Part II. Medicine, Surgery, and Midwifery.—H. Ackroyd, B.A., and L. E H R. Barker, B.A., Caius; J. R. Bentley, Emmanuel; G. T. Birks, B A., King's; A. R. Brailey, M.A., Downing; W. H. Brailey, M.A., Queens'; H. N. Burroughes B.A., Trinity; W. B. Crowfoot, B.A., Emmanuel; H. A. Cutler, M.A., Clare; W. F. L. Day, B.A., Caius; R. S Drew, B.A., Pembroke; E. A. Ellis, B.A., Downing; J. E. Frere, B.A., Pembroke; J. D. H. Freshwater, M.A., Trinity; E. V. Gostling, B.A., Caius; F. W. Goyder, B.A., St. John's; G. W. Greene, B.A., Downing; T. Guthrie, B.A., King's; W. L. Harnett, B.A., St. John's; W. Hill, B.A., Emmanuel; B. Hudson, B.A., Clare; H. L. P. Hulbert, M.A., and F. S. Kidd, B.A., Trinity; P. W. Leathart, B.A., Clare; H B. McCaskie, B.A., Caius; F. B. Manser, B.A., Peterhouse; G. W. Micklethwait, M.A., Trinity; P. K. Muspratt, B.A., Christ's; G. B. Norman, B.A., St. John's; P. N. Panton, B.A., Trinity; H. I. Pinches, B A., Sidney Sussex; F. Richmond, B.A., Clare; G. R. Rickett, B.A., King's; H. Robinson, B.A., Trinity; W. T. Scott, B.A., Clare; R. D. Smedley, M.A., Pembroke; J. E. Spicer, B A., Trinity; J. M. Stenhouse, B.A., Sidney Sussex; W. J. Susmann, B.A., Caius; B. N. Tebbs, M.A., Queens'; H. T. Thompson, M.A., Christ's; E. Weatherhead, St. John's; F. Whitaker, B.A., and L. E. Wigram, B.A., Trinity; H. L. Wilson, B.A., H. Selwyn; H. C. S. Woodward, M.A., Downing; and G. A. Wright, Christ's.

Royal College of Physicians and Royal College of Surgeons in Ireland.—The under-mentioned have passed the examination for the Conjoint Diploma in Public Health :—

A. Honours.—G. F. A. Smythe, F.R C.S. Edin., Lieutenant-Colonel R.A.M C., and J. Dorgon, M.B., B.Ch., Captain R.A.M.C.

B. Pass.—Geo. Hamill, F.R.C.S. Irel.; M. C. Beatty, L.R.C.P. and S., Lieutenant R.A.M.C.; R. A. Campbell, L.R.C.P. and S.; F. G. O'Donohue, L R.C.P. and S; John O'Hare, M.B., B.Ch.; W. C. Rivers, M.R.C.S.; and R. Huntly Nicholson, M.R.C.S., Colonel R.A.M.C.

Deaths of Eminent Foreign Medical Men.—The deaths of the following eminent foreign medical men are announced :—Dr. Eusebio Oehl, professor of physiology in the University of Pavia.—Dr. Nepveu, professor of pathological anatomy in the Marseilles Medical School.—Dr. La Bonnadière, professor of hygiene and therapeutics in the French Medical School, Beyrout.—Dr. G. Gevaert, *agrégé* in the Medical Faculty of the Brussels University.—Dr. Anton Bumm, professor of psychiatry in the University of Munich, at the age of 54 years. He had previously been professor in Erlangen. His best known papers are on the Physiology of the Brain and Nervous System.—Dr. Gustav von Veit, at Gevelsdorf in Pomerania, where he has been living since his retirement from the chair of Gynæcology in the University of Bonn some ten years ago. He may be considered as one of the founders of modern gynæcology, his name being more particularly connected with the introduction of the bimanual method of examination of the uterus and its appendages. He was in his eightieth year.

Royal College of Surgeons in Ireland—At a meeting of the President, Vice-President, and Council held on May 5th the following examiners were elected :—In anatomy: Ambrose Birmingham and Alexander Fraser. In surgery: F. Conway Dwyer, A. Fullerton, T. E. Gordon, and R. Lane Joynt. In physiology and histology: E. L'E. Ledwich and Charles Coppinger. In ophthalmology: Arthur H. Benson and Patrick W. Maxwell. In pathology and bacteriology: Arthur Hamilton White. In pathology: R. Allen. In midwifery and gynæcology: Frederick W. Kidd. In biology: John J. Burgess. In sanitary law and vital statistics: C. J. Powell. In engineering and architecture: J. Charles Wilmot. In dental surgery and pathology: Daniel Corbett, jun., and W. G. Story. In mechanical dentistry: George M. P. Murray and William Booth Pearsall. In chemistry and physics: Edward Lapper and R J. Montgomery. In languages: L. J. Woodroffe. In mathematics, physics, dictation, and English essay: J. W. Tristram—A meeting of the Fellows will be held on Saturday, May 30th, at 1 P.M., to receive the annual report of the council A meeting will also be held on Monday, June 1st, at 1 P.M., pursuant to the provisions of the charters, to elect a president, vice-president, council, and secretary of the College for the ensuing year. Fellows who may desire to have their names printed on the list of candidates for office are requested to signify their wish by letter to the registrar at the College on or before Tuesday, May 19th, as it is necessary to include the names in the voting papers which are forwarded to the Fellows and no candidate is eligible unless his application is received within the date specified.

Literary Intelligence.—The Scientific Press will shortly issue a small handbook entitled "A Practical Guide to Surgical Bandaging and Dressing," by W. Johnson Smith, F.R C.S. Eng.

Childhood Society.—A meeting of this society, which has for its object the scientific study of the mental and physical conditions of children, was held on May 11th at 7, St. James's-square, London, S.W., Earl Egerton of Tatton, the President, being in the chair.—Professor J. Edgar, M.A., Professor of Education in the University of St. Andrews, delivered an address on the Universities and Scientific Study of Children, with special reference to the Teaching Profession. The following motion, proposed by Mr. E. W. Brabrook, C.B., and seconded by Sir James Crichton Browne, F.R.S., was carried unanimously :—

> That it is desirable that the Elementary Education of Defective and Epileptic Children's Act, 1899, should be compulsory on educational authorities and that special training should be given at one or more training colleges for teachers who wish to qualify for the care of defective children. That the Government be requested to institute an inquiry into the best means of dealing with defective classes in after life and for determining the authority to be entrusted with that duty.

Parliamentary Intelligence.

HOUSE OF COMMONS.

Thursday, May 7th.

Small-pox in Liverpool.

Mr. Weir asked the President of the Local Government Board whether he was aware that when application was made to the clerk to the sanitary authority of Liverpool for permission to search the list of small-pox patients which he was required to keep under the Vaccination Act, 1898, the applicants were sent to the various small-pox hospitals for the purpose of inspecting the registers there; and whether arrangements could be made for the register to be kept in the clerk's office.—Mr. Grant Lawson, who replied, said: I understand that the hospital committee of the town council has imposed the obligation of making the entries in the small-pox register on the physician of the hospital and that the register is available at the office of the hospital for any person who desires to inspect it. I am informed by the town clerk that arrangements could be made for having it at some other office but that if this was done it would not be possible to keep the register so well up to date or so accurately as at present.

Mr. Weir also asked the President of the Local Government Board whether he was aware that the present epidemic of small-pox in Liverpool had already lasted for a period of six months, during which time there had been about 1400 cases and 90 deaths; and whether, seeing [illegible] would consider the advisability of [illegible] inspectors to inquire and to report [illegible] being adopted by the Liverpool [illegible] disease.—Mr. Grant Lawson, who replied, said: I am aware of the small-pox epidemic at Liverpool. At an early period of the outbreak one of the medical inspectors was directed to visit the district and to confer with the local authorities as to the measures to be taken and I have no reason to suppose that they are not doing their utmost in this matter. I may mention that the latest returns do not show that the epidemic is increasing.

Human Lymph.
